The example below first reads a structured value from the server, and then manipulates (changes) its elements. The modified value is then written to the server. In this case, the data type ID (and also the data type) can be taken over from what has been provided by the Read.

C#

```

13.2.10 Examples - OPC UA Interaction

13.2.10.1 Examples - OPC UA Interaction - Accept HTTPS certificate

The example below triggers the component to ask the user whether he/she wants to accept the server's HTTPS certificate.

C#

```
// This example shows how in a console application, the user is asked to accept a server HTTPS certificate.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.Interaction
{
    partial class AcceptCertificate
    {
        public static void Https()
        {
            // Do not implicitly trust any endpoint URLs. We want the user be asked explicitly.

EasyUAClient.SharedParameters.EngineParameters.CertificateAcceptancePolicy.TrustedEndpointUrlStrings.Clear();

            // Define which server we will work with.
            UAEndpointDescriptor endpointDescriptor = "https://opcua.demo-this.com:51212/UA/SampleServer/";

            // Instantiate the client object.
            var client = new EasyUAClient();

            UAAttributeData attributeData;
            try
            {
                // Obtain attribute data.
                // The component automatically triggers the necessary user interaction during the first operation.
```

```
                attributeData = client.Read(endpointDescriptor, "nsu=http://test.org/UA/Data/;i=10853");
            }
            catch (UAException uaException)
            {

13.2.11.2 Examples - OPC UA PubSub - Ethernet UADP mapping

C#

```
// This example shows how to subscribe to all dataset messages on an OPC-UA PubSub
connection with Ethernet UADP mapping.
//
// In order to produce network messages for this example, run the UADemoPublisher tool.
For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.
// The UADemoPublisher must be told to use the Ethernet transport: run it with the -eth
switch on the command line.
//
// The OpcLabs.Pcap assembly needs to be referenced in your project (or otherwise made
available, together with its
// dependencies) for the Ethernet transport to work, and additional software
installation may be needed as well. Refer to
// the documentation for more information.

VBScript

```
Rem This example shows how to subscribe to all dataset messages on an OPC-UA PubSub
connection with Ethernet UADP mapping.
Rem
Rem In order to produce network messages for this example, run the UADemoPublisher
tool. For documentation, see
Rem http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.
Rem
Rem The OpcLabs.Pcap assembly needs to be made available, together with its
dependencies, for the Ethernet transport to
Rem work, and additional software installation may be needed as well. Refer to the
documentation for more information.

13.2.11.3 Examples - OPC UA PubSub - Event pull

The example below subscribes to all dataset messages on an OPC-UA PubSub connection with UDP UADP mapping. The connection is specified by its physical parameters, using the scheme name "opc.udp" and the IP address of the multicast group to listen on.

C#

```
// This example shows how to subscribe to all dataset messages on an OPC-UA PubSub
connection, and pull events, and display
// the incoming datasets.
//
// In order to produce network messages for this example, run the UADemoPublisher tool.
For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.

13.2.11.7 Examples - OPC UA PubSub - Obtain all published datasets

The example below uses the ListAllPublishedDataSetNames Method to retrieve all published dataset from the PubSub configuration. The published datasets are actually organized in the PubSub configuration using a hierarchical structure of dataset folders. The word "all" in the method name denotes that the method will truly return all published datasets in the configuration, not just those at the "root" of the dataset folder structure, or in any specified dataset folder. The method will act recursively in the dataset folder structure, if needed. There are also methods that allow you to work with contents of individual dataset folders. Note that the published dataset names are unique across the PubSub configuration as a whole (regardless of their location in the dataset folder structure), and therefore a published dataset name is sufficient to identify the published dataset, and the dataset folder path is not strictly necessary.

C#

```
// This example obtains and prints out information about all published datasets in the
OPC UA PubSub configuration.
```

```

13.2.11.8 Examples - OPC UA PubSub - Obtain all PubSub components

The example below starts at the "root" of the PubSub configuration, and first obtains names of all PubSub connections available (they are at the 1st level). For each PubSub connection, given its name, it obtains names of writer groups configured on that PubSub connection (they are at the 2nd level). And, for each such writer group, given its name, it obtains names of all dataset writers configured on that writer group (they are at the 3rd level). Besides the PubSub object names, the commented parts also show how to obtain more detailed information about each PubSub object.

13.2.11.9 Examples - OPC UA PubSub - Resolve parameters from configuration file

C#

```
// This example shows how to subscribe to dataset messages and specify a filter, resolving logical
parameters to physical
// from an OPC-UA PubSub configuration file in binary format. The metadata obtained through the
resolution is used to decode
// fixed layout messages with RawData field encoding.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For
documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface
name to be used.

13.2.11.10 Examples - OPC UA PubSub - Resolve parameters given published dataset name

C#

```
// This example shows how to subscribe to dataset messages, specifying just the
published dataset name, and resolving all
// the dataset subscription arguments from an OPC-UA PubSub configuration file.
//
// In order to produce network messages for this example, run the UADemoPublisher tool.
For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.

VBScript

```
Rem This example shows how to subscribe to dataset messages, specifying just the
published dataset name, and resolving all
Rem the dataset subscription arguments from an OPC-UA PubSub configuration file.
Rem
Rem In order to produce network messages for this example, run the UADemoPublisher
tool. For documentation, see
Rem http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.

Option Explicit

Const UAPubSubResolverKind_PublisherFile = 3

```

```
                UAObjectIds.Server,
                New UABrowseParameters(UANodeClass.All,
{UAReferenceTypeIds.References}))
            Dim nodeId29 = CType(nodeElementCollection29(0), UANodeId)
            Console.WriteLine(nodeId29)
        End Sub
    End Class
End Namespace
```

VBScript

```
Rem This example shows different ways of constructing OPC UA node IDs.

Option Explicit

' A node ID specifies a namespace (either by an URI or by an index), and an identifier.
' The identifier can be numeric (an integer), string, GUID, or opaque.

Const UANodeClass_All = 255

' A node ID can be specified in string form (so-called expanded text).
' The code below specifies a namespace URI (nsu=...), and an integer identifier
(i=...).
' Assigning an expanded text to a node ID parses the value being assigned and sets all
corresponding
' properties accordingly.
Dim NodeId1: Set NodeId1 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId1.ExpandedText = "nsu=http://test.org/UA/Data/;i=10853"
WScript.Echo NodeId1

' Similarly, with a string identifier (s=...).
Dim NodeId2: Set NodeId2 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId2.ExpandedText = "nsu=http://test.org/UA/Data/;s=someIdentifier"
WScript.Echo NodeId2

' Actually, "s=" can be omitted (not recommended, though)
Dim NodeId3: Set NodeId3 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId3.ExpandedText = "nsu=http://test.org/UA/Data/;someIdentifier"
WScript.Echo NodeId3
' Notice that the output is normalized - the "s=" is added again.

' Similarly, with a GUID identifier (g=...)
Dim NodeId4: Set NodeId4 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId4.ExpandedText = "nsu=http://test.org/UA/Data/;g=BAEAF004-1E43-4A06-9EF0-
E52010D5CD10"
WScript.Echo NodeId4
' Notice that the output is normalized - uppercase letters in the GUI are converted to
lowercase, etc.

' Similarly, with an opaque identifier (b=..., in Base64 encoding).
Dim NodeId5: Set NodeId5 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId5.ExpandedText = "nsu=http://test.org/UA/Data/;b=AP8="
```

```
WScript.Echo NodeId5

' Namespace index can be used instead of namespace URI. The server is allowed to change
the namespace
' indices between sessions (except for namespace 0), and for this reason, you should
avoid the use of
' namespace indices, and rather use the namespace URIs whenever possible.
Dim NodeId6: Set NodeId6 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId6.ExpandedText = "ns=2;i=10853"
WScript.Echo NodeId6

' Namespace index can be also specified together with namespace URI. This is still
safe, but may be
' a bit quicker to perform, because the client can just verify the namespace URI
instead of looking
' it up.
Dim NodeId7: Set NodeId7 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId7.ExpandedText = "nsu=http://test.org/UA/Data/;ns=2;i=10853"
WScript.Echo NodeId7

' When neither namespace URI nor namespace index are given, the node ID is assumed to
be in namespace
' with index 0 and URI "http://opcfoundation.org/UA/", which is reserved by OPC UA
standard. There are
' many standard nodes that live in this reserved namespace, but no nodes specific to
your servers will
' be in the reserved namespace, and hence the need to specify the namespace with
server-specific nodes.
Dim NodeId8: Set NodeId8 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId8.ExpandedText = "i=2254"
WScript.Echo NodeId8

' If you attempt to pass in a string that does not conform to the syntax rules,
' a UANodeIdFormatException is thrown.
Dim NodeId9: Set NodeId9 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
On Error Resume Next
NodeId9.ExpandedText = "nsu=http://test.org/UA/Data/;i=notAnInteger"
If Err.Number = 0 Then
    WScript.Echo NodeId9
Else
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
End If
On Error Goto 0

' There is a parser object that can be used to parse the expanded texts of node IDs.
Dim NodeIdParser10: Set NodeIdParser10 =
CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.Parsing.UANodeIdParser")
Dim NodeId10: Set NodeId10 =
NodeIdParser10.Parse("nsu=http://test.org/UA/Data/;i=10853", False)
WScript.Echo NodeId10
```

```
' The parser can be used if you want to parse the expanded text of the node ID but do
not want
' exceptions be thrown.
Dim NodeIdParser11: Set NodeIdParser11 =
CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.Parsing.UANodeIdParser")

13.2.13.50 Examples - OPC Unified Architecture - Write and specify data type

The example below writes a single value, specifying the type to be written using a .NET Type.

Note that this example uses an overload of the WriteValue method that is not available in COM. If you are calling from a COM language or tool, use the WriteMultipleValues method instead. An example for that is given further down.

C#

```
// This example shows how to write a value into a single node, specifying a type
explicitly.
//
// Reasons for specifying the type explicitly might be:
// - The data type in the server has subtypes, and the client therefore needs to pick
the subtype to be written.
// - The data type that the server reports is incorrect.
// - Writing with an explicitly specified type is more efficient.
//
// For a selected subset of most common types, you can also use a different overload of
the WriteValue method, and specify
// a value from the TypeCode enumeration instead.

using System;
```

```
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    partial class WriteValue
    {
        public static void Type()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object
            var client = new EasyUAClient();

            // Modify value of a node
            try
            {
                client.WriteValue(
                    endpointDescriptor,
                    "nsu=http://test.org/UA/Data/;i=10221",
                    12345,
                    typeof(Int32));
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message);
            }
        }
    }

The example below writes multiple values, specifying the types to be written in the ValueType property, using a .NET Type.

Note that this approach is, at least theoretically, also available in COM languages and tools, but due to difficulties with obtaining the .NET Type, you are much more likely to specify the type using the ValueTypeCode or ValueTypeFullName property, for which the examples are given further down.

C#

```
// This example shows how to write values into 3 nodes at once, specifying a type
explicitly. It tests for success of each
// write and displays the exception message in case of failure.
//
// Reasons for specifying the type explicitly might be:
```

```
// - The data type in the server has subtypes, and the client therefore needs to pick
the subtype to be written.
// - The data type that the reports is incorrect.
// - Writing with an explicitly specified type is more efficient.
//
// Alternative ways of specifying the type are using the ValueTypeCode or
ValueTypeFullName properties.

>Message);
}
```

The example below writes multiple values, specifying the types to be written in the ValueTypeFullName property, using a string form of the .NET Type.

This approach is especially suitable in COM languages and tools, if you need to specify a type that is not covered by the TypeCode enumeration.

C#

```
// This example shows how to write values into 3 nodes at once, specifying a type's
full name explicitly. It tests for
// success of each write and displays the exception message in case of failure.
//
// Reasons for specifying the type explicitly might be:
// - The data type in the server has subtypes, and the client therefore needs to pick
the subtype to be written.
// - The data type that the reports is incorrect.
// - Writing with an explicitly specified type is more efficient.
//
// Alternative ways of specifying the type are using the ValueType or ValueTypeCode
properties.

                { _
                    New UAWriteValueArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10221", 23456), _
                    New UAWriteValueArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10226", 2.3456789), _
                    New UAWriteValueArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10227", "ABC") _
                } _
             )
            ' Production code would check the success of the operation. See separate example for
that.
        End Sub
    End Class
End Namespace
```

The example above can be extended by properly testing for success of each operation, like this:

C#

```
// This example shows how to write values into 3 nodes at once, test for success of each write
and display the exception
// message in case of failure.

13.2.15 Examples - Reactive Programming

13.2.15.1 Examples - Reactive Programming - Create OPC Data Access observable

The following code fragment creates the observable using one of the Create methods:

Creating OPC DA observable

```
DAItemChangedObservable<double> ramp =
     DAItemChangedObservable.Create<double>(
         "", "OPCLabs.KitServer.2", "Demo.Ramp", 1000);
```

13.2.15.2 Examples - Reactive Programming - Create OPC Data Access write observer

The following code fragment creates the observer using one of the Create methods:

Creating OPC DA write observer

```
DAWriteItemValueObserver<int> observer =
     DAWriteItemValueObserver.Create<int>(
         "", "OPCLabs.KitServer.2", "Simulation.Register_I4");
```

13.2.15.3 Examples - Reactive Programming - Transfer of OPC Data Access item values

In the example below, your application is required to continuously monitor the value of an OPC item, and when it is available (there is no failure obtaining the value), make some computations with it (we will multiply the value by 1000), and write the results into a different OPC item. This logic can be expressed by following code:

Reactive transfer of OPC DA item values

```
DAItemChangedObservable.Create<int>(
         "", "OPCLabs.KitServer.2", "Simulation.Incrementing (1 s)", 100)
     .Where(e => e.Exception == null)
     .Select(e => e.Vtq.Value * 1000)
     .Subscribe(DAWriteItemValueObserver.Create<int>(
         "", "OPCLabs.KitServer.2", "Simulation.Register_I4"));
```

Let's dissect what this example does:

1. It creates an observable sequence for significant changes in OPC-DA item "Simulation.Incrementing (1 s)".
2. The "Where" clause filters (from the observable sequence) only the changes that have a null Exception, i.e. those that carry a valid DAVtq object (value/timestamp/quality).
3. The "Select" clause takes the actual value from the Vtq property (it is of type DAVtq<int>), and returns the value multiplied by 1000.
4. An observer that writes incoming vales into the "Simulation.Register_I4" OPC-DA item is created.
5. The observer is subscribed to the transformed (processed) observable sequence.

14 Troubleshooting

This section is under construction and will be expanded in future versions.

14.1 Troubleshooting the Setup

In case of non-obvious installation problems, it might be helpful to view a detailed installation log. The installer creates a log file automatically. By default, it is located in the user's temporary directory, has a **".txt"** extension, and its name starts with **"Setup Log"** and it includes the date of the installation and a sequence number.

For example, the installation log file location and name might be:

"C:\Users\TestUser\AppData\Local\Temp\Setup Log 2014-11-03 #001.txt"

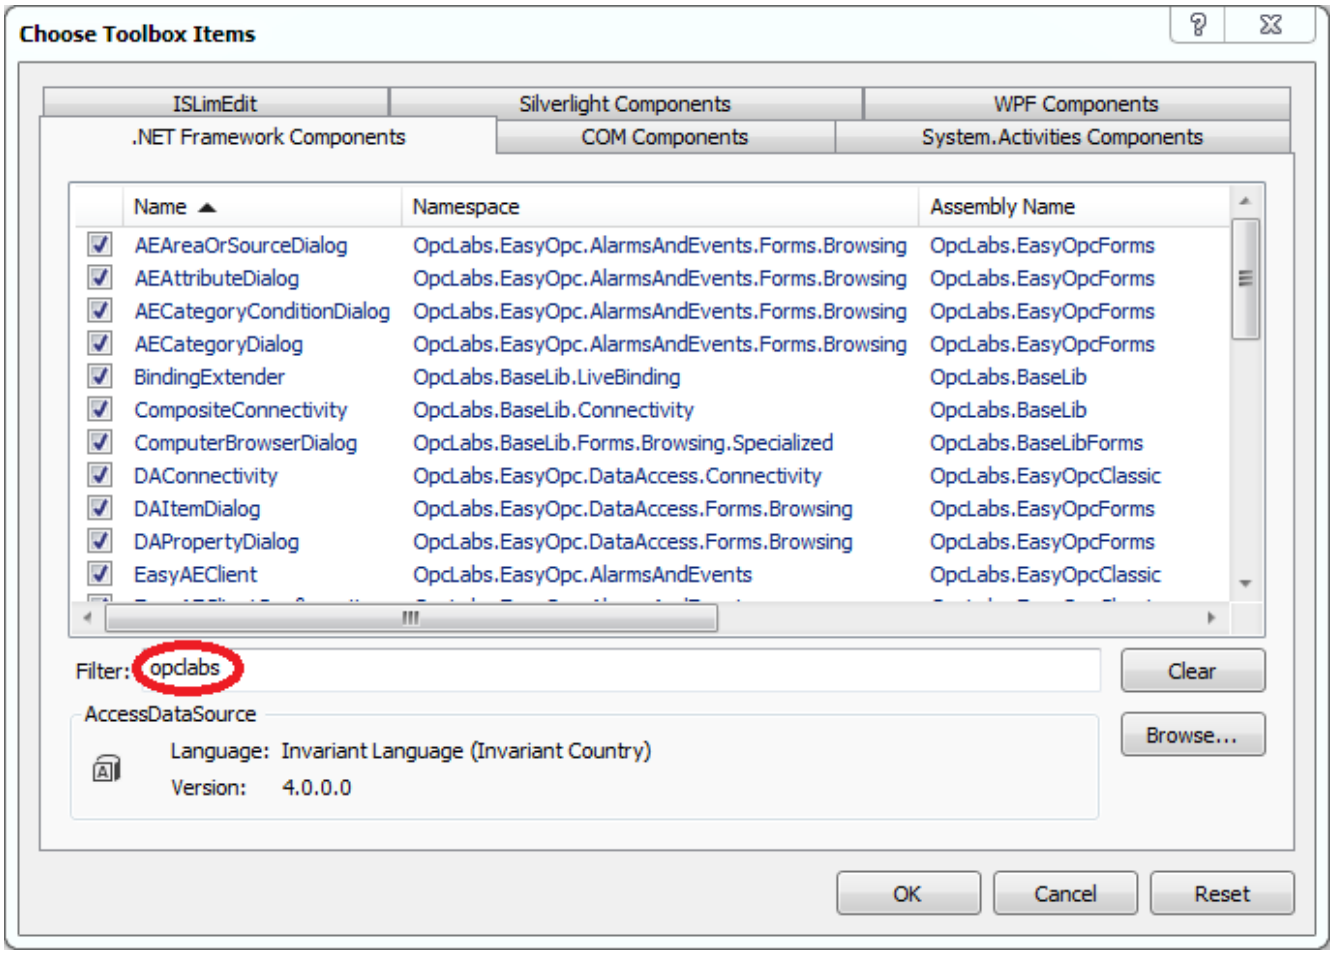
> ⚠ The "AppData" folder is hidden by default.

14.2 Troubleshooting Visual Studio Toolbox

QuickOPC toolkit items do not appear in the Toolbox

There should be tab labeled QuickOPC in the Visual Studio Toolbox, and contain the toolbox items described in this document. The actual items displayed depend on the type of project and designer. In some cases, you may not have the QuickOPC tab or any QuickOPC items in the Toolbox, or if the set of items is incomplete.

1. Check that you are designing a supported project and item - such as Windows Forms form or control, or a WPF window. Make sure you have a document open in the editor that allows placing components to it – such as a Windows form (alternatively, "Show All" can be selected in the Toolbox).
2. Verify that your project (in its Properties) is targeting a supported version of .NET Framework. If not, retarget the project to a supported version. Commonly, if you do not see the right components, it means that your project is not targeting the .NET Framework version 4.7 or later.
3. Perform a "Reset Toolbox" command (right-click in the toolbox area first), and restart Visual Studio.
4. If everything else fails, you can add the OPC Data Client components to the Toolbox manually (you only need to this once): Right-click in the **Toolbox** area, and select "Choose Items...".



In the "**Choose Toolbox Items**" dialog, select "**.NET Framework Components**" tab (for Windows Forms or similar projects), or the "**WPF Components**" tab (for WPF), and type ***opclabs*** into the **Filter** field.

Then, check all boxes next to the displayed components, and press OK. The component icons should appear in the **Toolbox**. Note: they will only be visible in the proper context, i.e. when you have selected an appropriate parent component (usually, a Windows Form) in the designer, or when you check "Show All" in the Toolbox context menu.

You can create a new toolbox tab named "QuickOPC", and move the component icons into this tab. To create a new tab, right-click in the Toolbox area, and select "Add Tab".

14.3 Using packet capture files with OPC UA PubSub

OPC Data Client can read the OPC UA PubSub network traffic from a file, instead of using live data. This is extremely handy for various kinds of troubleshooting, diagnostics, analysis and similar tasks. It allows you to capture the data generated by the publisher once, and then replay it as many times as you like.

> In order to work with packet capture files, the OpcLabs.Pcap assembly and its dependencies are needed in runtime. For more information, see **OpcLabs.Pcap Usage (Section 5.1.5.1.5)**.

The network capture needs to be in the PCAP format. Various tools, including Wireshark, can read and write this format. The current versions of Wireshark, however, store network capture in a newer format (PCAPNG) by default. Using the "Save as type" drop-down in Wireshark's "Save file as" dialog, it is, however, easy to save your network captures in the PCAP format, or even convert existing PCAPNG captures to PCAP.

For UDP message mapping, call the UseUdpCaptureFile Extension Method on the PubSub connection descriptor object, passing it the name of the capture file to be used. For Ethernet message mapping, call the UseEthernetCaptureFile Extension Method instead.

The default file name extension is ".pcap".

C#

```
// This example shows how to feed the packet capture file into the PubSub subscriber, instead of connecting to
the message
// oriented middleware (receiving the messages from the network).
//
// The OpcLabs.Pcap assembly needs to be referenced in your project (or otherwise made available, together with
its
// dependencies) for the capture files to work. Refer to the documentation for more information.

```

When reading UDP message captures, there is a built-in IP fragment reassembler (for both IPv4 and IPv6), and thus you can work with messages whose requirements exceed the network's MTU.

The packets in the capture file are used to provide "timed" replay of the network communication. This means that when the capture is replayed, the software not only mimics the actual data in the packets, but it also attempts to maintain the same timing of the packets as it appears in the capture. An initial delay is added before the replay starts, in order to allow for startup tasks on the receiver side to finalize.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

15 Additional Resources

If you are migrating from earlier version, please read the "**What's New**" document (available from the Start menu or the Launcher application).

Study the **Reference (Section 16)** documentation (also available from Start menu).

Explore the **Examples (Section 13)** and Bonus Material associated with the product.

Check the vendor's Web page for updates, news, related products and other information.

16 Reference

The reference is provided online. The printable documentation (PDF booklet) only contains introductory chapters for each kind of reference material, and links to the online content.

We have put together the references to the most commonly used types in the **Concise Reference (Section 16.1)** page.

16.1 Concise Reference

This page contains links to reference material for the most commonly used types.

16.2 .NET Assemblies Reference

The reference is both for .NET Framework and .NET Standard development platforms, although parts of the documentation may not apply, or may slightly differ depending on the platform.

In This Topic

List of .NET assemblies

- OpcLabs.BaseLib Assembly
- OpcLabs.BaseLibForms Assembly
- OpcLabs.BaseLibPresentation Assembly
- OpcLabs.EasyOpcClassic Assembly
- OpcLabs.EasyOpcForms Assembly
- OpcLabs.EasyOpcUA Assembly
- OpcLabs.OpcComplexEventProcessing Assembly

16.3 COM Type Libraries Reference

List of COM type libraries

- OpcLabs_BaseLib ActiveX DLL
- OpcLabs_BaseLibForms ActiveX DLL
- OpcLabs_EasyOpcClassic ActiveX DLL
- OpcLabs_EasyOpcForms ActiveX DLL
- OpcLabs_EasyOpcUA ActiveX DLL

The links above may not work in Microsoft Help Viewer (Visual Studio) due to a bug in the software we use to create the documentation and help. Following links to the Web-based (online) help can be used instead:

- OpcLabs.BaseLib ActiveX DLL
- OpcLabs.BaseLibForms ActiveX DLL
- OpcLabs.EasyOpcClassic ActiveX DLL
- OpcLabs.EasyOpcForms ActiveX DLL
- OpcLabs.EasyOpcUA ActiveX DLL

Usage notes

The COM objects of OPC Data Client are based upon the underlying .NET objects. In order to avoid duplicities and mismatches, the documentation is primarily maintained for the .NET objects. The .NET objects are exposed using the "interop" mechanism to the COM world using an automated translation provided by Microsoft. Therefore, a documentation that applies to a .NET type or member that is exposed to COM can be assumed to apply to the corresponding .NET type or member as well.

The bulk of the reference documentation for COM type libraries is generated from the type libraries themselves. This means that only a limited descriptive text (typically, one line) is available with each type or member. You need to look to the reference documentation for the .NET assemblies in order to find the more detailed documentation.

In addition, some languages or COM-based tools do not make direct use of the type libraries, and therefore require some additional effort to use the COM objects - such as knowing their ProgIDs, dealing with interface IDs (IIDs), etc.

Below are some rules and conventions that help with using the reference documentation for COM.

Determining the assembly name

This is not usually needed, but may be useful if you are writing a setup program for your application, and want to deploy only the .NET assemblies that are needed to run the COM objects that you are actually using.

The .NET assembly has the same name as its corresponding type library, except that the .DLL extension is used instead of .TLB.

For example, in order to use types from the **OpcLabs.EasyOpcUA.tlb** type library, the **OpcLabs.EasyOpcUA.dll** assembly is needed. Note that due to assembly dependencies, some more assemblies may be needed as well.

In This Topic

Determining the name of the corresponding .NET object

For a COM object, you need to locate the corresponding .NET object in order to find more detailed documentation related to the object.

The .NET objects that corresponds to the COM object has the same simple name, but is qualified with some namespace. Use the Search functionality of the help system to find the reference documentation for the .NET object, typing in the name of the COM object you are interested in.

For example, the EasyUAClient COM object corresponds to OpcLabs.EasyOpc.UA.EasyUAClient object in .NET.

Determining a CLSID of the object

The CLSID may be needed to create a COM object in some languages (e.g. C++).

In order to determine the CLSID of the COM object, first find the reference documentation for its corresponding .NET object. The CLSID is then listed as the GuidAttribute of this .NET object.

Determining a ProgID of the object

The CLSID may be needed to create a COM object in some languages (e.g. VBScript).

In order to determine the CLSID of the COM object, first find the reference documentation for its corresponding .NET object. The ProgID is then same as the fully qualified name of that type (i.e. including the namespace). For example, for the EasyUAClient COM object, the ProgID is "**OpcLabs.EasyOpc.UA.EasyUAClient**".

Determining the default COM interface

The default COM interface is the interface that implements the members of the COM object. You need to locate the reference documentation for the default interface to find more detailed information related to the object.

The default COM interface has the same name as the COM object, but is preceded with an underscore ('_'). In order to view the reference documentation for the default COM interface, first find the reference documentation for the .NET object that corresponds to the COM object you are interested in. On the Overview page of that .NET object, you will see the list of interfaces that the object implements. Click on the interface that starts with an undescore and has the same name as the object.

For example, the default COM interface for EasyDAClient object is named _EasyDAClient.

Determining the IID of the default COM interface

The IID may be needed to access the COM object in some languages (e.g. C++).

In order to determine the IID of the default COM interface, first find the reference documentation for this interface. The IID is then listed as the GuidAttribute of this interface.

16.4 Format Strings Reference

Formatting converts objects to strings, usually for display purposes. OPC Data Client follows the design of formatting in the .NET Framework (https://msdn.microsoft.com/en-us/library/26etazsy(v=vs.110).aspx).

Certain OPC Data Client objects implement the IFormattable interface, and can therefore participate in formatting schemes provided by the .NET Framework – e.g. their formatting can be controlled by corresponding format specifiers in the String.Format method overloads. This appendix describes the formatting of OPC Data Client types that have this kind of support.

In this part of the Reference:

- OperationResult Format Strings
- ValueResult Format Strings

- DAQuality Format Strings
- DAVtq Format Strings
- DAVtqResult Format Strings

- UAAttributeData Format Strings
- UAAttributeDataResult Format Strings

16.5 Point Types Reference

A point represents a discrete real-time value source or target. Points are used

- in Live Binding Model, and
- in Connectivity RTD Server (Excel Option).

This reference currently focuses on describing the so-called friendly syntax used in Connectivity RTD Server for various types of points.

In this part of the Reference:

- **OPC-DA Item Point (Section 16.5.1.1)**
- **OPC-DA Property Point (Section 16.5.1.2)**

- **OPC-UA Attribute Point (Section 16.5.1.3)**

16.5.1 Point Types Reference

16.5.1.1 OPC-DA Item Point

An **OPC-DA Item Point** is a connectivity point that represents an OPC Data Access (OPC-DA) item.

Point, Parameters, and Arguments Types

For operations listed below, following classes are used for the point itself, the operation parameters and operation arguments:

In This Topic

Operation	Point Type	Parameters Type	Arguments Type
Read	DAItemPoint Class	DAItemPointReadParameters Class	DAItemPointReadArguments Class
Subscribe		DAItemPointSubscribeParameters Class	DAItemPointSubscribeArguments Class
Write		DAItemPointWriteParameters Class	DAItemPointWriteArguments Class

Type Aliases

You can use following type aliases for this point type:

- **opcdaitem**
- **di**

Friendly Topic Syntax

In order to describe the point and its subscription parameters, use the following sequence:

```
ServerDescriptorString, ItemId [, RequestedUpdateRate]
```

Where:

- *ServerDescriptorString* is a descriptor string for the server.
- *ItemId* is an OPC item identifier (empty string for the root).
- *RequestedUpdateRate* is the requested update rate (how often should the updates be received). In milliseconds. Defaults to 1000 milliseconds.

If the point or parameters differ from the default in other properties, the friendly topic syntax cannot be used.

Remarks

The *ServerDescriptorString* may contain one of the following:

- A server class, i.e. ProgID (or {CLSID}) of the object.
- A string in the form "\\machineName\serverClass".
- A URI of the object.

Examples

```
"OPCLabs.KitServer.2", "Demo.Ramp"

"OPCLabs.KitServer.2", "Demo.Ramp", "5000"

"opcda://MY-PC/OPCLabs.KitServer.2", "Demo.Single"
```

XML Topic Syntax

The XML topic syntax is capable to fully describe the point and parameters. It is currently not documented, and is subject

to change.

16.5.1.2 OPC-DA Property Point

An **OPC-DA Property Point** is a connectivity point that represents an OPC Data Access (OPC-DA) property.

In This Topic

Point, Parameters, and Arguments Types

For operations listed below, following classes are used for the point itself, the operation parameters and operation arguments:

Operation	Point Type	Parameters Type	Arguments Type
Read	DAPropertyPoint Class	Object (see Note 1)	DAPropertyPointReadArguments Class
Subscribe		Object (see Note 1)	DAPropertyPointReadArguments Class (see Note 2)

The Write operation is not supported. The Subscribe operation make a on-time Read (in OPC-DA terms, Property "Get").

Note 1: No specific parameters are needed.

Note 2: Arguments for the Subscribe operation reuse the type used with the Read.

Type Aliases

You can use following type aliases for this point type:

- **opcdaproperty**
- **dp**

Friendly Topic Syntax

In order to describe the point and its subscription parameters, use the following sequence:

```
ServerDescriptorString, ItemId, { QualifiedName | PropertyId }
```

Where:

- *ServerDescriptorString* is a descriptor string for the server.
- *ItemId* is an OPC item identifier (empty string for the root).
- *QualifiedName* is a qualified name of the property (used with OPC XML-DA). Must contain a colon (:).
- *PropertyId* is a symbolic or numeric value of the property ID. Case insensitive.

If the point or parameters differ from the default in other properties, the friendly topic syntax cannot be used.

Remarks

The *ServerDescriptorString* may contain one of the following:

- A server class, i.e. ProgID (or {CLSID}) of the object.
- A string in the form "\\machineName\serverClass".
- A URI of the object.

For valid symbolic values of the *PropertyId*, see DAPropertyIds Enumeration Fields.

Examples

```
"OPCLabs.KitServer.2", "Demo.Ramp", "DataType"

"opcda://MY-PC/OPCLabs.KitServer.2", "Demo.Single", "5"
```

XML Topic Syntax

The XML topic syntax is capable to fully describe the point and parameters. It is currently not documented, and is subject to change.

16.5.1.3 OPC-UA Attribute Point

An **OPC-UA Attribute Point** is a connectivity point that represents an OPC Unified Architecture (OPC-UA) attribute on a node.

In This Topic

Point, Parameters, and Arguments Types

For operations listed below, following classes are used for the point itself, the operation parameters and operation arguments:

Operation	Point Type	Parameters Type	Arguments Type
Read	UAAttributePoint Class	UAAttributePointReadParameters Class	UAAttributePointReadArguments Class
Subscribe		UAAttributePointSubscribeParameters Class	UAAttributePointSubscribeArguments Class
Write		UAAttributePointWriteParameters Class	UAAttributePointWriteArguments Class

Type Aliases

You can use following type aliases for this point type:

- **opcuaattribute**
- **ua**

Friendly Topic Syntax

In order to describe the point and its subscription parameters, use the following sequence:

```
EndpointDescriptorString, NodeId [, [AttributeId] [, SamplingInterval]]
```

Where:

- *EndpointDescriptorString* is a descriptor string for the endpoint, i.e. a URL string of the resource.
- *NodeId* is a node Id. Contains an identifier for a node in a server's address space, together with a complete namespace URI.
- *AttributeId* identifies an attribute of a node. It can be symbolic or numeric value. Case insensitive. Defaults to the **Value** attribute.
- *SamplingInterval* is the fastest rate at which the monitored items should be accessed and evaluated (in milliseconds). Defaults to 1000 milliseconds.

If the point or parameters differ from the default in other properties, the friendly topic syntax cannot be used.

Remarks

For valid symbolic values of the *AttributeId*, see UAAttributeId Enumeration Fields.

Examples

```
   "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=11218"

   "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=11218", "DataType"

   "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=11218", , "5000"
```

XML Topic Syntax

The XML topic syntax is capable to fully describe the point and parameters. It is currently not documented, and is subject to change.
