OPC Data Client User's Guide

Version 2020.2

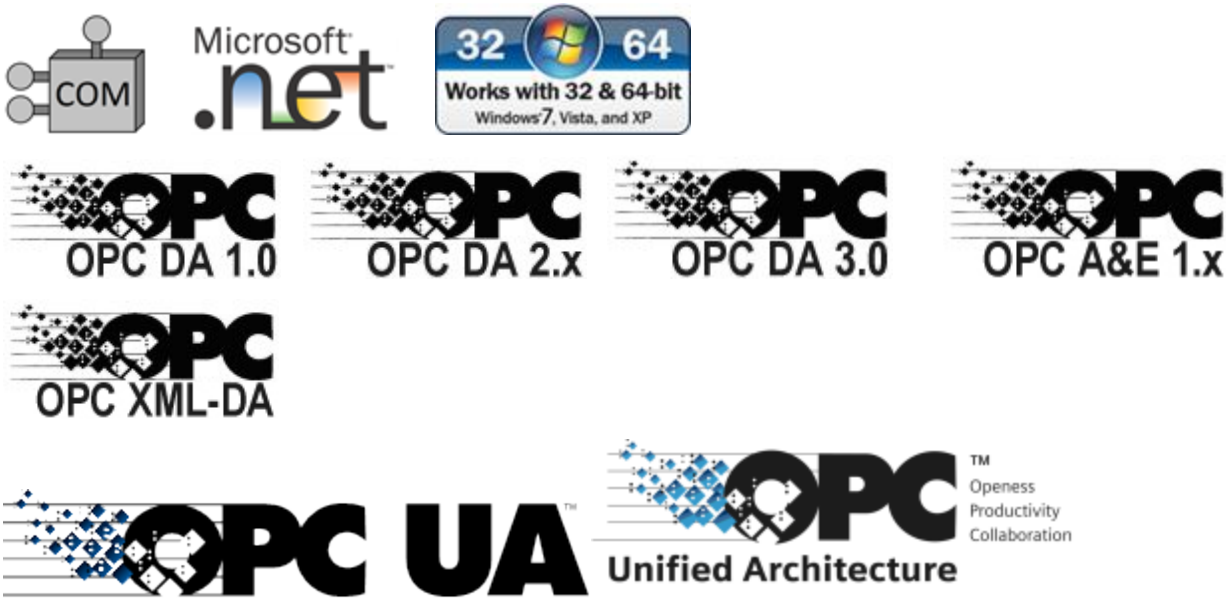
2 Introduction

Are you having difficulties incorporating the OPC data into your solution? Need to do it quickly and in quality? If so, OPC Data Client comes to the rescue.

OPC Data Client is a radically new approach to access OPC data. Traditionally, OPC programming required complicated code, no matter whether you use OPC custom or automation interfaces, or OPC Foundation SDKs. In OPC "Classic" world (COM/DCOM based), OPC Server objects must be instantiated, OPC Group objects must be created and manipulated, OPC Items must be added and managed properly, and subscriptions must be established and maintained. Other hurdles exist in OPC Unified Architecture (OPC-UA), such as proper server endpoint discovery, security policy negotiation, etc. Too many lines of error-prone code must be written to achieve a simple goal – reading or writing a value, or subscribing to value changes.

OPC Data Client is a set of components that simplify the task of integrating OPC into applications. Reading a value from an OPC server, writing a data value, or subscribing to data changes can be achieved in just one or two lines of code! Receiving alarms from OPC Alarms and Events server is also easy.



Notes:

- This documentation is for OPC Data Client version 2020.2. This is known as the *external version* of the product. The *internal version* number is 5.58.

2.1 Terminology

OPC Data Client is a name for the product as a whole. It can be used from various languages and environments.

Parts of the product can be differentiated by the kind of OPC specifications they deal with. OPC Data Client-Classic refers to parts of the product that deal with "Classic" OPC specifications, based on COM/DCOM (or OPC XML). It can be used

from COM tools or from .NET. Similarly, the OPC Data Client-UA referts to parts of the product that deal with OPC Unified Architecture (OPC UA) specifications, and it also supports both .NET and COM development targets.

The other way to differentiate the parts of the product is by the principal development technology they are aiming at: Either Microsoft .NET, or Microsoft .COM (so-called OLE Automation). When we need such disctinction, we refer to there product parts as OPC Data Client.NET or OPC Data Client-COM, respectively. When necessary, the differing text is marked with corresponding COM or .NET icon.

The following table explains the product part names, and how they relate to OPC specifications they cover, and to the development tools platform that can be used with them.

Development Tools/Target Platform:		**Microsoft .NET**	**Microsoft COM**
OPC Specifications			
OPC "Classic" (DCOM based)	OPC Data Access (OPC-DA)	OPC Data Client-Classic OPC Data Client.NET	OPC Data Client-Classic OPC Data Client-COM
	OPC Alarms and Events (OPC-A&E)		
OPC XML-DA (XML Data Access)			
OPC Unified Architecture (OPC-UA), for Data Access, Alarms & Conditions		OPC Data Client-UA OPC Data Client.NET	OPC Data Client-UA OPC Data Client-COM
OPC UA PubSub		OPC Data Client-UA OPC Data Client.NET	OPC Data Client-UA OPC Data Client-COM

The OPC XML-DA support in OPC Data Client.NET is transparently integrated into the component. Wherever this document refers to "OPC Data Access", it also usually applies to OPC XML-DA.

All products/product parts are delivered in a single installation package.

The main component of OPC Data Client is called EasyOPC, and it allows programmatic client access to OPC servers, Other parts of OPC Data Client are user interface objects (dialogs and controls), extensions, tools, and so on.

2.2 Product Editions

Following table will help you to understand the features of different OPC Data Client editions, and assist in selecting the edition that is best for you.

Product Edition:		**Standard**	**Professional**	**Enterprise** (new in 2019.2)	**Ultimate**	**Trial (free)**
Unlimited run time	The trial version delivers valid data for **30 minutes** since you have started your application. You then need to re-	✓	✓	✓	✓	×

	start the process in order to receive valid data again, and so on. Paid editions have **no such limitation**. *Contact us if you need a longer run time for your evaluation.*					
OPC Specifications						
OPC Data Access (4)	OPC-DA is the original specification. It is commonly used to move real-time data from PLCs, DCSs, and other control devices to HMIs and other clients, for display purposes and further processing.	✓	✓	✓	✓	✓
OPC XML-DA	OPC XML-DA specification builds on the OPC-DA specifications to communicate data in XML. It incorporates SOAP and Web services.	×	✓	✓	✓	✓
OPC Alarms and Events (4)	OPC-A&E provides alarm and event notifications on demand (in contrast to the continuous data flow of Data Access). These include process alarms, operator actions, informational messages, and tracking/auditing	×	✓	✓	✓	✓

	messages.					
OPC Unified Architecture (Generic/Data)	OPC-UA is the next generation of OPC. It brings the existing specifications together with a unified data model and uses Web services, rather than Microsoft COM, for messaging.	✓	✓	✓	✓	✓
OPC Unified Architecture (Methods)	The Method Service Set in OPC Unified Architecture allows the client to make function calls on OPC UA objects.	×	✓	✓	✓	✓
OPC Unified Architecture (Alarms & Conditions)	This standard deals with event subscriptions and notifications, Conditions, Dialog Conditions, and Alarms, including acknowledgement capabilities. Also includes specialized OPC UA Alarms and Conditions client object.	×	✓	✓	✓	✓
OPC UA PubSub	Subscriber functionality for OPC UA dataset messages distributed by message-oriented middleware, with support for resolution of parameters from the PubSub information model.	×	×	×	✓	✓

Development Models						
Imperative Programming Model (Section 5.1)	This is the traditional programming. You write code to instantiate objects, and call methods to perform the OPC operations.	✓	✓	✓	✓	✓
Live Binding Model (Section 5.3) [2]	Simply use the Visual Studio Designer to configure bindings between properties of visual or non-visual components, and OPC data. For Windows Forms and WPF, code-less.	×	✓	✓	✓	✓
Live Mapping Model (Section 5.2) [1]	Allows you to write objects that correspond logically to a functionality provided by whatever is "behind" the OPC data. You map your objects and members to OPC by annotating them with attributes.	×	×	✓	✓	✓
Reactive Programming Model (Section 5.4) [1]	High-level abstraction that allows you to compose asynchronous and event-based programs using data streams and LINQ-style query operators. Uses	×	×	×	✓	✓

	Microsoft Reactive Extensions (Rx) for .NET.					
Features						
Browsing Dialogs (Section 6.1.1)	Pre-made, highly configurable OPC browsing dialogs for Windows Forms (callable from WPF or COM applications as well). Provide interactive viewing and selection features.	×	✓	✓	✓	✓
Browsing Controls (Section 6.1.2) [(2)]	Configurable OPC browsing controls for Windows Forms. Can be combined with other controls on the form to achieve the desired functionality.	×	✓	✓	✓	✓
OPC UA Discovery (Section 5.1.2.3.5)	Local Discovery (LDS)	✓	✓	✓	✓	✓
	Network Discovery (LDS-ME)	×	✓	✓	✓	✓
	Global Discovery (GDS)	×	×	✓	✓	✓
Specialized Client Objects (Section 6.4)	- OPC UA Certificate Management Client (new in 2018.3) - OPC UA Global Discovery Client (new in 2018.3)	×	×	✓	✓	✓
	- OPC UA Publish-Subscribe Client. Provides access to PubSub information model	×	×	×	✓	✓

	in an OPC UA client, or to PubSub configuration stored in a file. (new in 2019.2)					
Extensions						
OPC UA Complex Data (Section 7.2.1)	Encodes and decodes OPC UA extension objects, according to data type dictionaries in the OPC UA information model.	×	×	✓	✓	✓
Development Platforms						
COM (3)	For languages or tools that supports Microsoft OLE Automation, e.g. Delphi, VB6, VBScript (such as in ASP), JScript, Perl, PHP, Python, VBA (such as in Excel), Visual FoxPro, REALbasic, Xbase, T-SQL, and many others. Also works from native C/C++.	×	✓	✓	✓	✓
.NET Framework (3)	For languages and tools based on Microsoft .NET Framework on Windows. Typical usage is from Visual Basic (VB.NET) or C#, but other languages can be used as well (e.g. PowerShell, managed C++, or F#).	✓	✓	✓	✓	✓

.NET Standard (new in 2018.3)	Multi-platform abstract API specification. Allows development in .NET languages for the .NET Core runtime on Windows or Linux.	×	✓	✓	✓	✓
Product Options (must be purchased as additional items)						
Excel Option (Section 12.1) (3)	Allows you to set up a communication link between Excel and any OPC server. It is possible to subscribe to and view real-time data, and also write the data back. No programming, macros or add-ins are necessary. With just drag-and-drop or copy-and-paste, you can create Microsoft Excel sheets with live, animated OPC data.	✓	✓	✓	✓	✓
StreamInsight Option (Section 12.2) (3)	Allows you to bring in streaming data from OPC sources into StreamInsight, analyze them and process them further, and even feed the results back to OPC servers. Data from OPC can be combined with data from multiple	×	×	✓	✓	✓

	other sources. You can monitor the data for meaningful patterns, trends and exceptions. Streaming OPC data can be analyzed and correlated while they are in-flight.					
Tools						
Connectivity Explorer (Section 11.2) (3)	Allows to navigate through hierarchy of OPC Data Access and OPC Unified Architecture servers and data nodes. You can subscribe to data changes, and view the results live.	✓	✓	✓	✓	✓
other tools	Launcher(3), License Manager(3) (GUI and Console), OPC UA Demo Publisher, OpcCmd Utility, UA Configuration Tool(3).	✓	✓	✓	✓	✓

Functionality of some Tools might be affected (limited) by the product edition in use.

Note (1): Only available under .NET Framework or .NET Standard development platforms.

Note (2): Only available under .NET Framework development platform (Windows).

Note (3): Only on Windows.

Note (4): Only available under COM or .NET Framework development platforms (Windows).

> ⚠ Licensing changes affecting the capabilities of various editions occur from time to time with releases of new OPC Data Client versions. Please re-check the edition capabilities if you are upgrading, or extending the upgrade assurance term.

The installation package and/or product packages or asemblies are the same, regardless of the product edition; the

enabled/allowed product capabilities are distinguished in the license key.

2.3 Development Platforms

OPC Data Client supports multiple development platforms. Not all functionality is available on every platform, however. The following table summarizes which functionalities are available where.

Development Platform:	**COM**	**.NET Framework**	**.NET Standard** (new in 2018.3)	**Excel** (with **Excel Option (Section 12.1)**)
Runtimes				
.NET Framework	✓	✓	✓	✓
.NET Core (new in 2018.3)	×	×	✓	×
Operating Systems				
Windows	✓	✓	✓	✓
Linux (new in 2018.3)	×	×	✓	×
OPC Specifications				
OPC Data Access	✓	✓	×	✓
OPC Alarms and Events	✓	✓	×	×
OPC XML-DA	✓	✓	✓	✓
OPC Unified Architecture - Generic/Data	✓	✓	✓	✓
OPC Unified Architecture - Alarms & Conditions	✓	✓	✓	×
OPC UA PubSub (new in 2019.2)	✓	✓	✓	×
Specialized OPC UA Facets				
Methods (Call service)	✓	✓	✓	× (1)
OPC UA Encodings (Client-Server)				
Binary	✓	✓	✓	✓
XML	✓	✓	×	✓
OPC UA Protocols (Client-Server)				
TCP (opc.tcp)	✓	✓	✓	✓
HTTP	✓	✓	×	✓
HTTPS	✓	✓	✓	✓
OPC UA PubSub Message Mappings				

UADP	✓	✓	✓	×
OPC UA PubSub Transport Protocol Mappings				
UDP (opc.udp)	✓	✓	✓	×
Ethernet (opc.eth)	✓	✓	✓	×
Development Models				
Imperative Programming Model (Section 5.1)	✓	✓	✓	× (1)
Live Binding Model (Section 5.3) (Windows Forms, WPF)	×	✓	×	×
Live Mapping Model (Section 5.2)	×	✓	✓	×
Reactive Programming Model (Section 5.4)	×	✓	✓	×
Real-time Data Spreadsheet	×	×	×	✓
Features				
Browsing Dialogs (Section 6.1.1)	✓	✓	×	× (1)
Browsing Controls (Section 6.1.2) (Windows Forms)	×	✓	×	×
Extensions				
OPC UA Complex Data (Section 7.2.1)	✓	✓	✓	✓
Distribution Formats				
Standalone Installer (Windows)	✓	✓	×	✓
NuGet Packages	×	✓	✓	×
Example Archives (new in 2018.3) (TGZ, ZIP formats)	×	✓	✓	×
Licensing				
License Location	See **Licensing Elements (Section 8.5)**			

Notes: (1) This functionality is not directly available on the development platform, but can be achieved by combining with VBA code (through COM platform).

OPC Data Client attempts to hide the differences caused by different implementations on various platforms and runtimes from the developer who uses it. It is not, however, always fully possible.

Throughout the documentation, we also try to pinpoint specific areas which are not available under some development platform or may work differently. There may be other, subtle differences under each platform as well. For example, the types of inner exceptions generated by the component may differ under various .NET Standard runtimes versus the code running on .NET Framework, unless the type of exception is documented. The error messages and other details of exceptions may differ as well.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

'Support' means that OPC Data Client is designed to work and tested on the environment, and vendor's technical support may be contacted for assistance with OPC Data Client on the environment. Support may be not available for operating systems, .NET runtimes and other dependencies that are past their active lifecycle at the time of support request, even if they were supported at the time of product release.

> .NET Standard is basically just an abstract API specification, with multiple runtimes (such as .NET Core) available that fulfill the specification. .NET Framework, on the contrary, is both an API specification and a concrete runtime. Listing them here side by side as two distinct target development platforms might seem improper, but it is not a misunderstanding of the concepts. It is intentional and appropriate, as this is how the OPC Data Client usages needs to be distinguished in terms of development and deployment.

2.3.1 Transitioning from .NET Framework to .NET Standard

If you have previously developed with OPC Data Client for .NET Framework and are now transitioning to .NET Standard, you may continue to use your existing code, as there are practically no coding differences between the two. There are, however, differences in other aspects, such as the supported functionality, tooling, installation, security, user interface, deployment, use of examples, etc.

For easier transition, we recommend that you read the following articles, which cover the areas that specifically need your attention.

(Section 2.3)

- **Development Platforms (Section 2.3)**: Overview of the development platforms, and how OPC Data Client differs on them.
- **.NET Runtimes (Section 2.4.1)**
- **Operating Systems (Section 2.4.2)**
- **Development Tools (Section 2.5)**
- **Installing NuGet Packages in JetBrains Rider (Section 3.1.2.3)**
- **Getting Started under .NET Standard (Section 3.3)**
- Security: **OPC UA Directory Certificate Stores (Section 4.13.1.4.1)**
- User Interface: **Console Interaction (Section 6.1.4.1)**
- Deployment: **Automated deployment, roll your own (Section 8.1.2)**; **Deployment Prerequisites (Section 8.2)**; **Installing Assemblies (.NET) (Section 8.3.1)**
- **Managed Resource License Store (Section 8.5.1)**
- **Supported OPC Specifications (Section 9.1)**; **Supported OPC UA Profiles (Section 9.1.1)**
- **.NET Standard Examples (Section 13.1.3)**

2.4 Requirements

Topics in this part describe OPC Data Client requirement in terms of:

- **.NET Runtimes (Section 2.4.1)**

- **Operating Systems (Section 2.4.2)**
- **Hardware (Section 2.4.3)**

Related to this, but not considered a requirement per se, are **Development Tools (Section 2.5)**. This is because OPC Data Client can be used from wide range of tools, and none is strictly required.

2.4.1 .NET Runtimes

.NET Framework, COM, and Excel Development

If you are developing under .NET Framework or COM development platform, and also for Excel development with the **Excel Option (Section 12.1)**, (at least) one of the following .NET runtimes must be installed on your development and production computers:

- .NET Framework 4.7
- .NET Framework 4.7.1
- .NET Framework 4.7.2
- .NET Framework 4.8

In This Topic

Note that

- .NET Framework 4.7 is included with Windows 10 version 1703 (Creators Update).
- .NET Framework 4.7.1 is included with Windows 10 version 1709 (Fall Creators update).
- .NET Framework 4.7.2 is included with Windows 10 version 1803 (April 2018 Update), version 1809 (October 2018 Update), Windows Server versions 1803 and 1809, and Windows Server 2019.
- .NET Framework 4.8 is included with Windows 10 version 1903 (May 2019 Update).

.NET Standard Development

If you are developing under .NET Standard development platform, (at least) one of the following .NET runtimes must be installed on your development computer:

- .NET Core 2.1.2 - 2.1.14
- .NET Core 3.1.0 - 3.1.1

On the production computers, you can either use framework-dependent deployment (FDD), and in such case one of the above runtimes must be installed on the production computer, or you can use a self-contained deplyment (SCD), in which case the .NET runtime you have selected does not have to be preinstalled on the production computer (but it is deployed along with your application). See .NET Core application deployment for more information.

.NET Core

On Linux, you may find Prerequisites for .NET Core on Linux page useful, in order to check the supported Linux distributions/versions, and what other dependencies exist. Related to this, you may also want to review:

- .NET Core versioning article
- .NET Core Supported OS Lifecycle Policy article
- Microsoft Support for .NET Core article

If you want to verify the version of .NET Core on your computer, use the ***dotnet --info*** command in the command prompt, and look for the **Version** field under **"Microsoft .NET Core Shared Framework Host"**, or (in newer versions) under **".NET Core runtimes installed:"** in the generated output. Do not use ***dotnet --version***, because this command only returns the version of the .NET Core command-line tools.

Other Runtimes for .NET Standard

Other .NET runtimes for the .NET Standard that are not listed here (Mono, Xamarin, UWP, .NET Framework) are not supported. It is possible that OPC Data Client will work on such .NET runtimes as well, but if you decide to use them, you are on your own... OPC Data Client may support them in the future.

Remarks

For a (incomplete) list of .NET Runtimes OPC Data Client has been tested with, consult Knowledge Base article QuickOPC Compatibility Test List.

The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

'Support' means that OPC Data Client is designed to work and tested on the environment, and vendor's technical support may be contacted for assistance with OPC Data Client on the environment. Support may be not available for operating systems, .NET runtimes and other dependencies that are past their active lifecycle at the time of support request, even if they were supported at the time of product release.

2.4.2 Operating Systems

.NET Framework, COM, and Excel Development

In This Topic

This chapter describes the operating systems supported if you are developing under .NET Framework or COM development platform, and also for Excel development with the **Excel Option (Section 12.1)**.

The product is supported on following **client operating systems**:

- Microsoft Windows 7 (x86 or x64) with SP1
- Microsoft Windows 10 (x86 or x64) Fall Creators Update (version 1709) or later

The product is supported on following **server operating systems**:

- Microsoft Windows Server 2012 (x64)
- Microsoft Windows Server 2012 R2 (x64)
- Microsoft Windows Server 2016 (x64)
- Microsoft Windows Server 2016 Core (x64) *(see **Server Core Systems (Section 2.4.2.1)** for limitations on this type of system)*

- Microsoft Windows Server 2019 (x64)
- Microsoft Windows Server 2019 Core (x64) *(see **Server Core Systems (Section 2.4.2.1)** for limitations on this type of system)*

On x64 platforms, OPC Data Client can run in 32-bit or 64-bit mode.

.NET Standard Development

This chapter describes the operating systems supported if you are developing under .NET Standard.

With **.NET Core** runtime, OPC Data Client supports following operating systems in general:

- Linux
- Microsoft Windows

The precise versions supported depend on the .NET runtime you have chosen, and on its version. Refer to the documentation of the particular .NET runtime for more information.

Linux

For .NET Core: See Microsoft articles .NET Core Supported OS Lifecycle Policy, and Linux Prerequisites.

Microsoft Windows

For .NET Core: See Microsoft articles .NET Core Supported OS Lifecycle Policy, and Windows Prerequisites.

Other Operating Systems for .NET Standard

Other operating systems on which .NET Core can run but are not listed here (macOS) are not supported. It is possible that OPC Data Client will work on such operating systems as well, but if you decide to use them, your are on your own... OPC Data Client may support them in the future.

Remarks

For a (incomplete) list of operating systems OPC Data Client has been tested with, consult Knowledge Base article QuickOPC Compatibility Test List.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

'Support' means that OPC Data Client is designed to work and tested on the environment, and vendor's technical support may be contacted for assistance with OPC Data Client on the environment. Support may be not available for operating systems, .NET runtimes and other dependencies that are past their active lifecycle at the time of support request, even if they were supported at the time of product release.

2.4.2.1 Server Core Systems

Some Microsoft Windows Server systems are categorized or can be installed as **Server Core** systems. They have no graphical user interface for management, and have some other limitations too.

OPC Data Client does not support development work on Server Core systems, but you can run programs created with OPC Data Client on them.

You should use the Production Installer (or your own installation method for the application your are creating) to install OPC Data Client on the Server Core system. If you attempt to run the Full Installer on the Server Core, it will show a warning message. If you proceed with the installation using the Full Installer anyway, the product will install, and will work well for production purposes (runtime), but some features will not work. For example, no links installed by the Setup program will be functional, because they rely on the shell functionality that is not present in Server Core. No shortcuts are installed onto desktop, and to the Start menu (as there is no such thing on Server Core).

The Server Core systems are meant for programs with no graphical user interface. If you run a GUI program developed with OPC Data Client on a Server Core system, it will most likely work - but that's not what the system was meant to be for. Ideally, your programs for Server Core should be services, Web apps, console applications, and such. There are also some limitations to what the GUI parts of OPC Data Client can do on Server Core. For example:

- Launching a browser by clicking on a URL in the controls or dialogs provided by OPC Data Client will not work.
- The ComputerBrowserDialog dialog (using Windows Shell) does not work.

> If you are scratching your head trying to get the installation files onto the Server Core box, see e.g. Getting installation files onto Server Core.

'Support' means that OPC Data Client is designed to work and tested on the environment, and vendor's technical support may be contacted for assistance with OPC Data Client on the environment. Support may be not available for operating systems, .NET runtimes and other dependencies that are past their active lifecycle at the time of support request, even if they were supported at the time of product release.

2.4.3 Hardware

OPC Data Client minimal hardware requirements are the same as those for the operating system and the development tools you are using.

For installation on Windows using the Full Installer, you should have at least 680 MB of free hard disk space before installing OPC Data Client.

2.5 Development Tools

In This Topic

Development Tools under .NET Framework

The development tools we have targeted primarily are:

- Microsoft Visual Studio 2017 (all editions, including Community).
- Microsoft Visual Studio 2019 (all editions, including Community).

Microsoft Visual Studio 2013 and 2015 may still work for many tasks, but we do not test for that.

The .NET Framework projects you create need to target .NET Framework 4.7 or higher.

In OPC Data Client.NET and OPC Data Client-UA for .NET, the available examples show how the components can be used from C#, Visual Basic.NET, and managed C++. Windows Forms, ASP.NET pages, console applications, and WPF applications are all supported.

Development Tools under .NET Standard

The development tools we have targeted primarily are:

- .NET Core CLI Tools
- JetBrains Rider 2019.1
- Visual Studio 2019
- Visual Studio Code (with the C# extension)

Other tools are likely to work as well. Also, some older versions of the development tools may work; we do not, however, test with them or support them.

When targeting the .NET Core runtime, .NET Core SDK 2.1.400 or higher is needed for development.

Development Tools under COM

In OPC Data Client-COM and OPC Data Client-UA for COM, the available examples show how the components can be used from Visual Basic (VB), C++, VBScript (e.g. in ASP, or Windows Script Host), JScript, Object Pascal (in Delphi), PHP, Visual Basic for Applications (VBA, e.g. in Excel), Visual FoxPro (VFP), and other tools. Any tool or language that supports COM Automation is supported.

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

2.6 Licensing

OPC Data Client is a licensed product. You must obtain a license to use it in development or production environment. The legal aspect of the OPC Data Client licensing requires you to comply with the terms of its End User License Agreement (EULA). The technical aspect of the OPC Data Client licensing requires that for both the development and runtime purposes, you install or or otherwise provide a license key file that you have obtained with the OPC Data Client purchase (unless you are evaluating the product, in which case the built-in trial license can be used).

The license key is in a file, typically with .BIN or .TXT extension.

When you develop for .NET Framework, COM or Excel platform, the licenses are installed and managed using a **License Manager (Section 11.1)** utility (GUI, or console-based **LMConsole Utility (License Manager Console) (Section 11.1.1)**), described further in this document.

When developing for .NET Framework or .NET Standard platform, you can embed the license key in a managed resource directly in your program. For details, see **Managed Resource License Store (Section 8.5.1)**.

Trial License

For evaluation purposes, you are granted a trial license, which is in effect if no other license is available. The OPC Data Client.NET, OPC Data Client-UA and OPC Data Client-COM parts are licensed together.

With the trial license, the components only provide valid OPC data for 30 minutes since the application was started. After this period elapses, performing OPC operations will return an error. Restarting the application gives you additional 30 minutes, and so on. If you need to evaluate the product but the default trial license is not sufficient for your purposes, please contact the vendor or producer, describe your needs, and a special evaluation license may be provided to you.

Other Licensing Considerations

When using OPC Data Client, you also need to comply with **Licenses for 3rd-party Material (Section 2.6.1)** included with the product.

License to code from OPC Foundation

OPC Data Client includes code from OPC Foundation, such as OPC UA stack. Some of that code is released under dual-license model: RCL (Reciprocal Community License) applies to OPC Foundation corporate members, while GPL 2.0 applies to other users. Since OPC Data Client has been developed and is distributed by an OPC Foundation corporate member, GPL 2.0 does not apply to users of OPC Data Client.

3rd-party licenses when targeting .NET Standard

> ⚠ When you target **.NET Standard** development platform (see **Development Platforms (Section 2.3)**), OPC Data Client assemblies depend on (but do not ship with or include) various 3rd-party NuGet packages (mainly from Microsoft, and OPC Foundation). When you reference any of the OPC Data Client NuGet packages, you also need to consent to licensing conditions of the dependent packages (and their dependencies, recursively). As with the material directly included with OPC Data Client, we have limited our choice of dependent packages to those with **highly permissive licenses** that will not limit you unnecessarily. It always remains your responsibility to review the precise license terms and comply with them.

Optional 3rd-party libraries under LGPL or other licenses

OPC Data Client includes some libraries licensed under GNU Lesser General Public License (LGPL) or other licenses. They are only needed in special cases described in the documentation. You do not have to include them in your deployment unless you need to actually use the specific features they support. When you do not include them, LGPL does not apply.

For example, the PacketDotNet and SharpPcap libraries are only necessary if you want to use OPC UA PubSub Ethernet mapping, or work with Wireshark capture files.

2.6.1 Licenses for 3rd-party Material

OPC Data Client uses 3rd-party licensed material from different sources, and this material is redistributed with OPC Data Client. By using OPC Data Client, you are also bound by the license conditions of any material redistributed with OPC Data Client. The licenses that apply are listed here.

We always consider the effects of including such material with the product, and try to minimize the use of 3rd party if possible. We attempt to select **highly permissive licenses** that will not limit you unnecessarily. We do not use copyleft licenses such as GPL that would restrict your work to the same license terms as they have.

There are two typical usage scenarios:

1. You install OPC Data Client and use it to develop software. In this case, the usage is covered by OPC Data Client and its documentation, and you normally do not have to do anything special to fulfill the license conditions for the material redistributed with OPC Data Client .

2. You redistribute and/or deploy the software that you have developed with OPC Data Client. In this case, the licenses for the redistributed material (below) typically do not require you to do more than to make a corresponding attribution in the software and/or its documentation.

   Some of the material redistributed with OPC Data Client is **never redistributed** with your own application, and some **may not be redistributed in your particular case**, depending on which elements of OPC Data Client you use in your application. In such cases you may skip the licenses that do not apply to your redistribution. For details on this, see the **Application Deployment (Section 8)** section (**Licenses for Redistributed Material (Section 8.5.3)**).

It always remains your responsibility to comply with the precise license conditions of OPC Data Client EULA and the material listed below.

⚠ Do not use the list below to assess which license conditions will apply to the project you develop with OPC Data Client. Material listed below applies to OPC Data Client as a whole, and contains many pieces that are only used in supporting, non-redistributable tools and utilities, or during development time. Such licenses do not apply to your project you develop. See **Licenses for Redistributed Material (Section 8.5.3)** for the list that applies to the projects developed with OPC Data Client..

3 Getting Started

This section of the documentation consists of following parts:

- **Installation (Section 3.1)**
- **Getting Started under .NET Framework (Section 3.2)**,
- **Getting Started under .NET Standard (Section 3.3)**, and
- **Getting Started under COM (Section 3.5)**.

Depending on your development platform, please refer to the corresponding part.

For Getting Started related to OPC UA PubSub, see

- **Getting Started with OPC UA PubSub under .NET (Section 3.4)**

For Getting Started articles for various product options, see

- for Excel Option: **Getting Started under Excel (Section 12.1.2)**, and
- for StreamInsight Option: **StreamInsight Option Installation and Getting Started (Section 12.2.2)**.

3.1 Installation

OPC Data Client comes in two *distribution formats*:

- **Setup Program (Section 3.1.1)**. This is what you get when you directly download the software from the Web site, or obtain it on a distribution media such as CD or flash disk. The Setup program is only available for Windows. Use the Setup program mainly if you are targeting .NET Framework, COM, or Excel development platform.
- **NuGet Packages (Section 3.1.2)** (NuGet is a package manager for development tools such as Visual Studio). The packages are hosted on www.nuget.org, and you need to use a NuGet client in order to access them. Use the OPC Data Client NuGet packages when you are targeting the .NET Standard as a development platform. In the absence of a setup program, OPC Data Client provides several smaller downloads that complement the NuGet packages - such as archive files with examples, etc.

The distribution formats are described further below in this chapter.

Included Software

The OPC Data Client setup program does not install other software on the target system.

Related products

Additional products exist to complement the base OPC Data Client offering. Check the options available with your vendor.

3.1.1 Setup Program

The Setup program is only available for Windows. Use the Setup program mainly if you are targeting .NET Framework, COM, or Excel development platform.

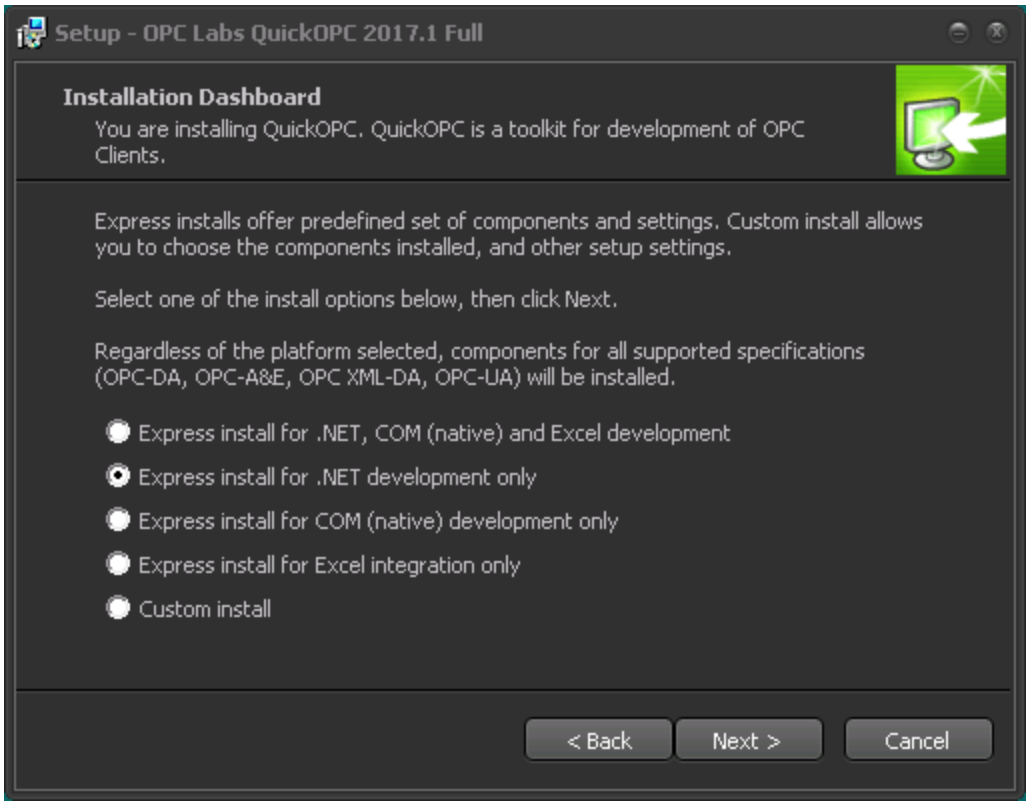
3.1.1.1 Running the Setup

The installation can be started by running the setup program. Just follow the on-screen instructions. The installation program requires that you have administrative privileges to the system.

The installation package file is code-signed, increasing security, improving trust, and providing better download experience from the Web. We use “COMODO RSA Code Signing CA” certificate. The name of signer is “CODE Consulting and Development, s.r.o.”. Certain other items in the product (such as the executables of the License Manager and OPC Kit Server, and the Help files, are also code-signed, using the same certificate).

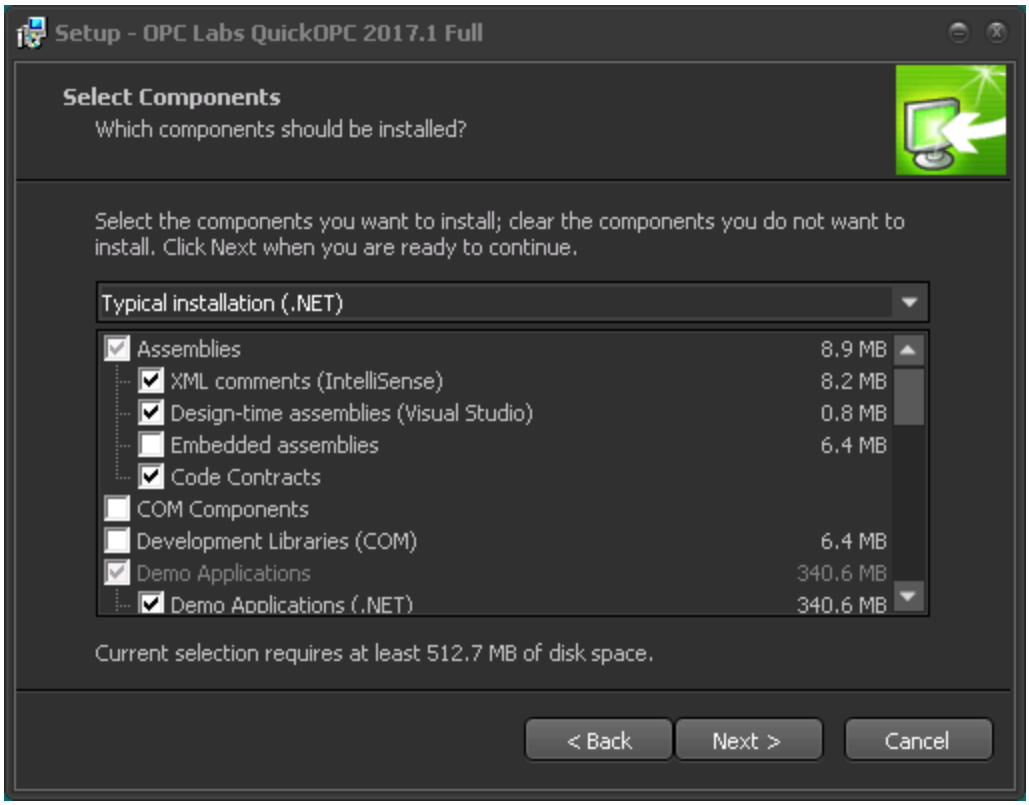
The installation wizard start with an introductory screen:

After an introductory screen, the setup wizard offers you the basic installation options:



For start, simply choose one of the “express” install options. If you decide to select “custom install”, the installation program then offers you several installation types, and also allows you to choose specifically which part of the product to install. In addition, with the “custom install”, you can also influence additional settings such as the destination location, and whether to automatically launch the License Manager utility.

For “custom install”, the component selection wizard page looks like this:



After the installation, the Start menu contains a number of hierarchically organized icons for various parts of the product. There is also a "Product Folder" shortcut, which opens the directory where all product files reside, making it easier to locate them.

When the installation is finished, it opens the Launcher application. This application is a switchboard that presents the same shortcuts as those available from the Start menu. It serves as a starting point for work with OPC Data Client.

The Setup program also places a Launcher application shortcut to the desktop, to the Programs group (Start menu), and to the Quick Launch bar (note that Quick Launch isn't visible by default; to enable it, see https://support.microsoft.com/en-us/kb/975784).

When the installation is finished, it also opens the Getting Started section of the documentation. You can also access the documentation and various tools from your Start menu, or the Launcher application that is installed together with the product.

When installing version OPC Data Client, it is strongly recommended that you first uninstall any version numbered between 5.00 and 5.31, instead of simply applying the installation over the previous version. The reason for this that the earlier versions installed the runtime assemblies into the Global Assembly Cache (GAC), whereas versions 5.32 and later do not do this by default. Having older assemblies in the GAC while developing with newer assemblies outside of the GAC is possible in principle, but without extra precautions, it can lead to all kinds of mix-ups and confusion.

The full standalone installer has a German localization. When the Setup programs detects that current user's UI language is German, it automatically switches to this localization.

If the needs of your organization require you to automate the installation of QuickOPC, it is possible to do so, using switches on the command line (see http://www.jrsoftware.org/ishelp/index.php?topic=setupcmdline). For additional information, see a related article in the Knowledge Base, Full installer Types, Components and Tasks. Note that for production purposes, it is not expected that you will automate the full installer in this way; you should be using the production installer instead (see the Application Deployment section).

For those who want to use the command-line interface, a "Command Prompt From Here" link is installed into the product folder. This link allows you to switch from the Windows Explorer to a CMD window with the current directory set to the chosen place, for quick experiments and exploration.

3.1.1.2 Uninstallation

The product includes an uninstall utility and registers itself as an installed application in Windows. It can therefore be removed easily from Control Panel. Alternatively, you can also use the Uninstall icon located in the product's group in the Start menu or the Launcher application.

You can uninstall OPC Data Client using following steps (*x.yz* denotes the version you have installed):

1. Go to **Windows Control Panel** and select "Uninstall a program". In the list of programs, locate "OPC Data Client *x.yz* Build *m.n*", and double-click on it. Alternatively, from **Windows Start menu**, select All programs -> OPC Labs -> OPC Data Client *x.y* -> Uninstall.

2. Press the "Yes" button when asked whether you are sure to uninstall.

These instructions are also available from the Start menu as a HTML document. To access them, select All programs -> OPC Labs -> OPC Data Client *x.y* -> Uninstall Instructions.

The uninstallation does not remove the OPC Data Client licenses present on the system in **Registry License Store (Section 8.5.2)**.

3.1.2 NuGet Packages

NuGet packages are for development on .NET Standard and .NET Framework platforms. Use the **Setup Program (Section 3.1.1)** when developing for COM or Excel platform.

In This Topic

NuGet (www.nuget.org) is the package manager for the Microsoft development platform including .NET. The NuGet client tools provide the ability to produce and consume packages. OPC Data Client NuGet packages are hosted in the NuGet Gallery (https://www.nuget.org/packages). The NuGet Gallery is the central package repository used by all package authors and consumers.

When you use NuGet to install a package, it copies the library files to your solution and automatically updates your project (add references, change config files, etc.). If you remove a package, NuGet reverses whatever changes it made so that no clutter is left.

For more details about OPC Data Client NuGet packages and instructions on how to use them, see:

- **List of Packages (Section 3.1.2.1)**
- **Installing NuGet Packages in Visual Studio (Section 3.1.2.2)**
- **Installing NuGet Packages in JetBrains Rider (Section 3.1.2.3)**
- **Installing NuGet Packages using .NET Core CLI Tools (Section 3.1.2.4)**

Limitations

Note that NuGet is primarily a tool for resolving build-time dependencies. The amount of functionality that you get through OPC Data Client NuGet packages is smaller than what OPC Data Client can actually do for you. If you want a full coverage of the features, you would be better off installing the product using the Setup program. Further below you will

find a list of differences between the two distribution forms.

The bulk of this documentation assumes that you have installed the product using the Setup program. You need to keep the limited scope of NuGet in mind when interpreting the documentation.

What is included in the NuGet packages:

- Runtime assemblies for all OPC specifications and programming models (for .NET Framework and .NET Standard target platforms).
- User interface components (OPC browsing dialogs and browsing controls for Windows Forms).
- IntelliSense support (XML comments).
- Examples in LINQPad. This means that whenever you reference one of the OPC Data Client NuGet packages in LINQPad, LINQPad will automatically add the OPC Data Client examples under its "Samples" tab.

What is only available from the Setup program or elsewhere (e.g. online):

- Support for COM development (VB6, PHP, Excel, Delphi and similar tools).
- Documentation and Help.
- Visual Studio integration, including Live Binding design-time support (codeless creation of OPC applications).
- Examples and Demo applications, Bonus.
- OPC Data Access simulation server, test tools.
- License Manager utility.
- StreamInsight Option, Excel Option.

3.1.2.1 List of Packages

Following OPC Data Client NuGet packages are available from www.nuget.org :

- **OpcLabs.QuickOpc**: OPC client components for all environments and project types (for .NET Framework and .NET Standard target platforms).
- **OpcLabs.QuickOpc.Forms**: Components that are specific for Windows Forms (can be partially used from WPF as well).

Following NuGet packages with OPC Data Client examples exist and are available from www.nuget.org :

- **OpcLabs.QuickOpc.Sample.CS**: Console-based QuickOPC examples in C# (source code).
- **OpcLabs.QuickOpc.Sample.VB**: Console-based QuickOPC examples in VB.NET (source code).

The strings in **bold** are the package IDs.

3.1.2.2 Installing NuGet Packages in Visual Studio

Note that before installing the NuGet packages, you need to create a Visual Studio project of the desired type. The NuGet packages get installed "into" the project.

In This Topic

Using Package Manager GUI

Using Package Manager Console

This text assumes that you are using Visual Studio 2017. With other tools, the procedures may be different, but should be reasonably similar.

In order to install a OPC Data Client NuGet package and reference it from your project using the **Package Manager GUI**:

1. In the Visual Studio Solution Explorer window, right-click the project, and select Manage NuGet Packages.
2. Make sure that **Package source** is set to "**nuget.org**".
3. Type ***QuickOPC*** into the Search box. A list of available OPC Data Client packages appears.
4. Click on the package you are interested in. Its details appear in the pane next (right) to it.
5. If needed, select a specific version of the package.
6. Press the Install button. A **Preview** windows appears, summarizing the changes that are about to be made.
7. Review the changes, and press the OK button.
8. The NuGet client will now update your project as needed. Among other things, it will download and copy over the OPC Data Client assemblies, and reference them.
9. A "**readme.txt**" file appears in the editor, with additional information. It is recommended that you read the file.
10. You can now start using the types from the referenced OPC Data Client assemblies.

If you do not see the packages in the NuGet Package Manager, make sure your project's framework is set to .NET Framework 4.7 or later, or .NET Core 2.1 and later.

Using Package Manager Console

This text assumes that you are using Visual Studio 2017. With other tools, the procedures may be different, but should be reasonably similar.

In order to install a OPC Data Client NuGet package and reference it from your project using **Package Manager Console**:

1. In the Visual Studio, select Tools -> NuGet Package Manager -> Package Manager Console.
2. Make sure that **Package source** is set to "**nuget.org**".
3. In the **Default project** drop-down, select the project.
4. Enter command ***Install-Package Id***, where *Id* is the package ID of the package to install (for example, **OpcLabs.QuickOpc**). Press ***Enter***.
5. The NuGet client will now update your project as needed. Among other things, it will download and copy over the OPC Data Client assemblies, and reference them.
6. A "**readme.txt**" file appears in the editor, with additional information. It is recommended that you read the file.
7. You can now start using the types from the referenced OPC Data Client assemblies.

3.1.2.3 Installing NuGet Packages in JetBrains Rider

Note that before installing the NuGet packages, you need to create a Rider project of the desired type. The NuGet packages get installed "into" the project.

This text assumes that you are using JetBrains Rider 2018.1. With other versions, the procedures may be different, but should be reasonably similar.

In order to install a OPC Data Client NuGet package and reference it from your project

1. Switch to the **NuGet** window in the Rider; if it is not visible, use View -> Tool Windows -> NuGet (***Alt+7***) command

from the menu.
2. In the **NuGet** window, switch to the **Packages** tab.
3. Make sure that package sources (the second control to the right of the search box) include "**nuget.org**".
4. Type ***QuickOpc*** into the search box.
5. Select the package you are interested in under **Available Packages** list in the left pane of the window. Its details appear in the pane next (right) to it.
6. If needed, select a specific version of the package in the upper part of the right pane.
7. In the right pane, press the green + button next to the name of your project.
8. Press the Yes button when asked to confirm the installation of the package.
9. The NuGet client will now update your project as needed. Among other things, it will download and copy over the OPC Data Client assemblies, and reference them.
10. You can now start using the types from the referenced OPC Data Client assemblies.

3.1.2.4 Installing NuGet Packages using .NET Core CLI Tools

Note that before installing the NuGet packages, you need to create a .NET Core project of the desired type. The NuGet packages get installed "into" the project.

> Use this procedure also when your development environment is Visual Studio Code.

In order to install a OPC Data Client NuGet package and reference it from your project:

1. Open a command prompt.
2. Navigate to the directory of your project.
3. Type the following: ***dotnet add package OpcLabs.QuickOpc***. This command adds OPC Data Client package reference to the project file.

   > The above command actually adds a reference to the package corresponding always to the very latest OPC Data Client version. If you want to be sure that you referencing a package for OPC Data Client 2020.2, use ***dotnet add package OpcLabs.QuickOpc --version 5.58*** command instead.

4. If you need to add more packages (see **List of Packages (Section 3.1.2.1)**), repeat the ***dotnet add package*** command, giving it the package Id as an argument.

3.2 Getting Started under .NET Framework

This section of the documentation consists of following parts:

- **Getting Started with OPC Classic under .NET Framework (Section 3.2.1)**, and
- **Getting Started with OPC UA under .NET (Section 3.2.2)**.

Depending on whether you develop OPC "Classic" or OPC Unified Architecture applications for Microsoft .NET Framework, please refer to the corresponding part.

3.2.1 Getting Started with OPC Classic under .NET Framework

OPC Data Client.NET allows you to develop using various development models. In this Getting Started chapter, we will present two of them:

- **Making a first OPC Data Client.NET application using Live Binding in Windows Forms (Section 3.2.1.1)** (without any coding), and
- **Making a first OPC Data Client.NET application using traditional coding (Section 3.2.1.2)** (imperative programming).

The Live Binding model also works with Windows Presentation Foundation (WPF); for a related Getting Started see **Making a first OPC UA application using traditional coding (Section 3.2.2.3)**.

Other development models available are *live mapping*, and *reactive programming (Rx)*.

3.2.1.1 Making a first OPC Classic application using Live Binding in Windows Forms

In this Getting Started procedure, we will create a Windows Forms application in C# or Visual Basic that subscribes to OPC Data Access (OPC-DA) item and continuously displays it changes. The live binding model allows achieving this functionality by simply configuring the OPC Data Client components, without any manual coding.

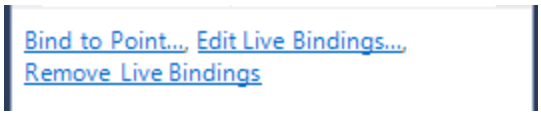
1. Install OPC Data Client. Make sure that you have selected an installation choice that includes .NET development.
2. Start Microsoft Visual Studio, and create new Visual C# or Visual Basic project, selecting "Windows Forms Application" template. **Make sure that in the upper part of the "New Project" dialog, the target framework is set to ".NET Framework 4.7" or later.**
3. Drag the DAConnectivity component from the "**QuickOPC**" tab of the **Toolbox** to the form's design surface.

   Notice that three icons will appear below the form: One labeled "daConnectivity1", the second labeled "pointBinder1", and the third labeled "bindingExtender1".

   If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

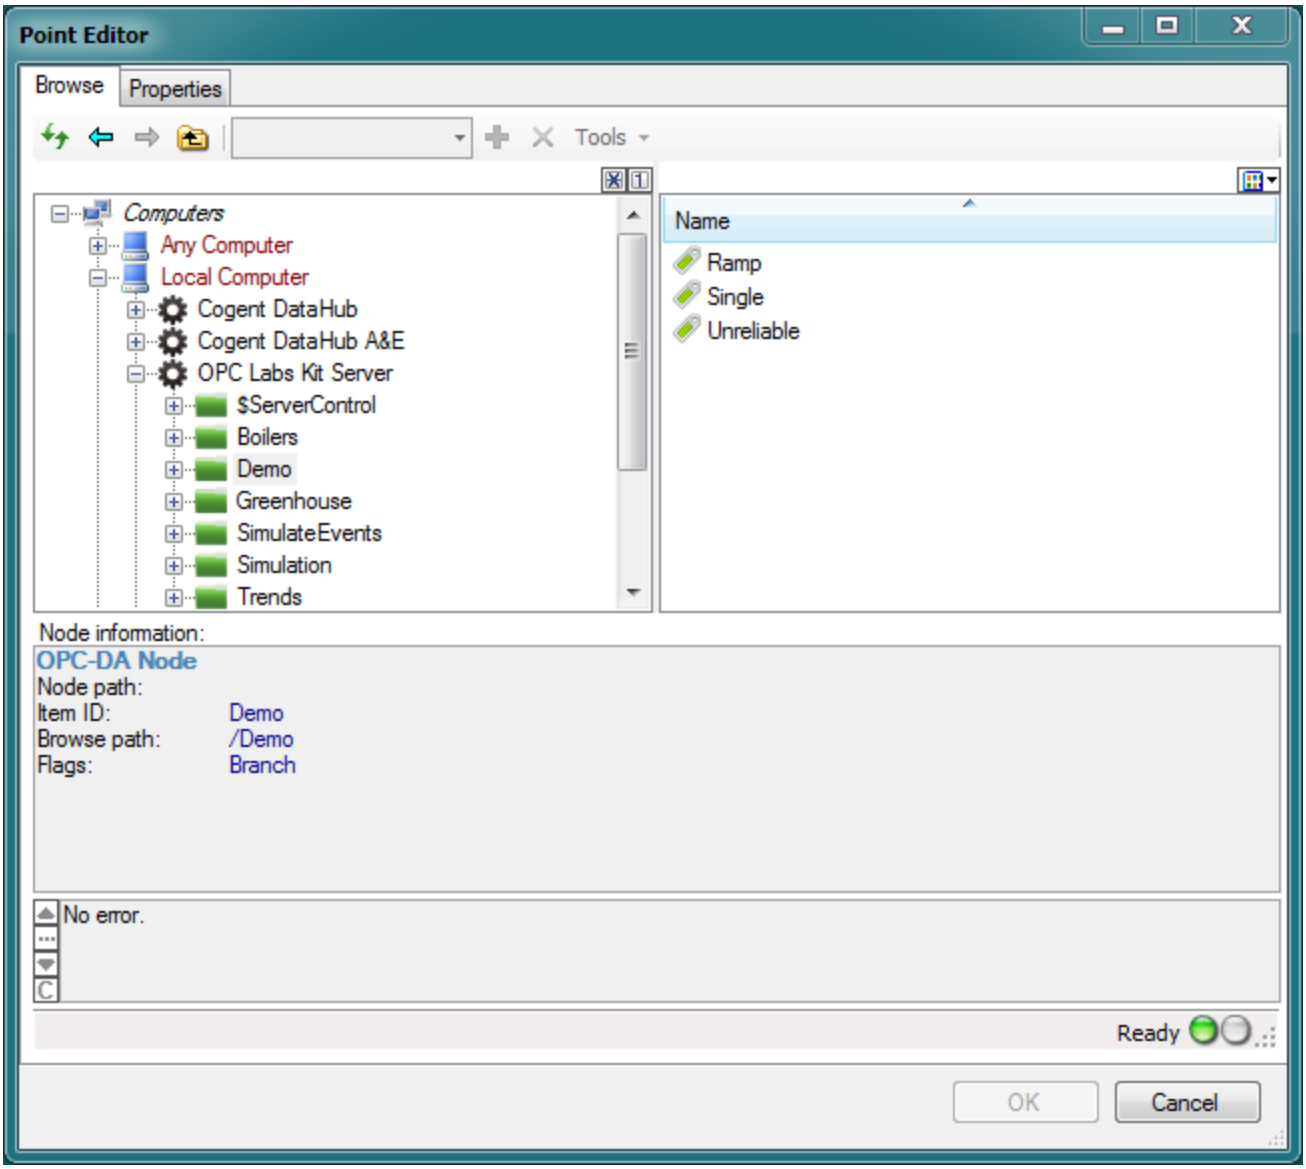
4. Drag a standard TextBox from the **Toolbox** to the form.
5. Right-click on the text box control on the form, and choose "Bind to Point" command.

   Alternatively, you can select the text box control first, and then choose the "Bind to Point" command in the Properties window; for this to work, however, the commands must be displayed in the **Properties** window.



If you do not see these commands, display them by right-clicking in the **Properties** window, and checking "Commands" in the menu.

6. In the "**Point Editor**" dialog, select Computers -> Local Computer -> OPC Labs Kit Server -> Demo -> Ramp, and press OK.



7. Build and run your application. You will see live OPC data changing in the text box. It is also possible to verify the effects of live binding without building the application: On the **bindingExtender** component placed on the form, select the "Design Online" command. This will cause Visual Studio to perform the live binding immediately. Use the "Design Offline" command to revert back to normal mode.

3.2.1.2 Making a first OPC Classic application using traditional coding

If you are interested in OPC Data Client.NET, your task will most certainly involve reading data from an OPC server. Here are a few steps that illustrate how to achieve that, using Microsoft Visual Studio, and a simple Windows Forms application in C#. The steps are quite similar if you are using other tools or a different programming language.

In This Topic

A Form to Read Value from OPC Data Access Server

We will create a form that will read a float value from the OPC server when loaded, and immediately display the formatted value in the text box on the form.

1. Install OPC Data Client. Make sure that you have selected an installation choice that includes .NET development.

2. Start Microsoft Visual Studio, and create new Visual C# project, selecting "Windows Forms Application" template. **Make sure that in the upper part of the "New Project" dialog, the target framework is set to ".NET Framework 4.7" or later.**

3. Instantiate the EasyDAClient component in the form: Drag the EasyDAClient component from the "**QuickOPC**" tab of the **Toolbox** to the form's design surface.

   An icon labeled "easyDAClient1" will appear below the form.

   If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

   Note: This is just shortcut way in Windows Forms to declaring and instantiating the component. In other environments, you can instantiate the component using the 'new' (C#) or 'New' (VB.NET) keyword, or any other way provided by the language or tool you are using.

4. Add a textbox to the form: Drag the TextBox component from the Toolbox to the form's design surface. The text box should appear on the form, and in the **Properties** window, you will see that it has been given a "textBox1" name.

5. Add handler for the Load event of the form: Select the form by clicking on its design surface. Then, in the **Properties** window, choose the "Events" view (orange lightning icon), and double-click the line with "Load" event (it is under **Behavior** group). A "Form1_Load" text in bold font will appear next to the event name, and a new event handler will be created for the Load event. The text editor will open for the code, and the caret will be placed into the Form1_Load method.

6. Add following code to the beginning of the **Form1.cs** file:

```
using OpcLabs.EasyOpc.DataAccess;
```

7. Write the event handler implementation. Add the following code to the body of Form1_Load method:

```
textBox1.Text = easyDAClient1.ReadItemValue("", "OPCLabs.KitServer.2",
"Demo.Single").ToString();
```

8. Build the project.

9. Run the application and observe the results. The text box on the form will be filled with a float value we have read from the OPC server, using a single code line!

A Form to Read Value from OPC XML-DA Server

We will create a form that will read a float value from the OPC server when loaded, and immediately display the formatted value in the text box on the form.

1. Install OPC Data Client. Make sure that you have selected an installation choice that includes .NET development.

2. Start Microsoft Visual Studio, and create new Visual C# project, selecting "Windows Forms Application" template. **Make sure that in the upper part of the "New Project" dialog, the target framework is set to ".NET Framework 4.7" or later.**

3. Instantiate the EasyDAClient component in the form: Drag the EasyDAClient component from the "**QuickOPC**" tab of the **Toolbox** to the form's design surface.

   An icon labeled "easyDAClient1" will appear below the form.

   If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

   Note: This is just shortcut way in Windows Forms to declaring and instantiating the component. In other environments, you can instantiate the component using the 'new' (C#) or 'New' (VB.NET) keyword, or any other way provided by the language or tool you are using.

4. Add a textbox to the form: Drag the TextBox component from the Toolbox to the form's design surface. The text box should appear on the form, and in the **Properties** window, you will see that it has been given a "textBox1" name.

5. Add handler for the Load event of the form: Select the form by clicking on its design surface. Then, in the **Properties** window, choose the "Events" view (orange lightning icon), and double-click the line with "Load" event (it is under **Behavior** group). A "Form1_Load" text in bold font will appear next to the event name, and a new event handler will be created for the Load event. The text editor will open for the code, and the caret will be placed into the Form1_Load method.

6. Add following code to the beginning of the **Form1.cs** file:

```
using OpcLabs.EasyOpc.DataAccess;
```

7. Write the event handler implementation. Add the following code to the body of Form1_Load method:

```
textBox1.Text = easyDAClient1.ReadItemValue(
    "http://opcxml.demo-this.com/XmlDaSampleServer/Service.asmx",
    "Dynamic/Analog Types/Double").ToString();
```

8. Build the project.

9. Run the application and observe the results. The text box on the form will be filled with a float value we have read from the OPC server, using a single statement!

Notes

If you are targeting an environment different from Windows Forms (such as console application, Web, or WPF), your steps will be similar. Instead of dragging the EasyDAClient component from the Toolbox, simply reference the **OpcLabs.EasyOpcClassic** assembly, and create a new instance of **OpcLabs.EasyOpc.DataAccess.EasyDAClient** object.

3.2.1.3 Where do I go from here?

You now have a basic idea of how to use the OPC Data Client.NET. There are many additional resources that you can use to gain additional knowledge about the product. Here are some of them:

- Play with the Demo applications (accessible from the Start menu or the Launcher application) and explore the various functionalities that the product provides.
- Read the User's Guide.
- Study the Reference documentation.
- Review the additional examples and tools included with the product.

3.2.2 Getting Started with OPC UA under .NET

OPC Data Client-UA allows you to develop using various development models. In this Getting Started procedure, we will present two of them:

- **Making a first OPC Data Client-UA application using Live Binding in Windows Forms (without any coding) (Section 3.2.2.1)**,
- **Making a first OPC UA application using Live Binding in WPF (Section 3.2.2.2)**, and
- **Making a first OPC Data Client-UA application using traditional coding (Section 3.2.2.3)** (imperative programming).

Other development models available are *live mapping*, and *reactive programming (Rx)*.

3.2.2.1 Making a first OPC UA application using Live Binding in Windows Forms

In this Getting Started procedure, we will create a Windows Forms application in C# or Visual Basic that subscribes to OPC Data

Access (OPC-DA) item and continuously displays it changes. The live binding model allows achieving this functionality by simply configuring the OPC Data Client components, without any manual coding.

1. Install OPC Data Client. Make sure that you have selected an installation choice that includes .NET development.
2. Start Microsoft Visual Studio, and create new Visual C# or Visual Basic project, selecting "Windows Forms Application" template. **Make sure that in the upper part of the "New Project" dialog, the target framework is set to ".NET Framework 4.7" or later.**
3. Drag the UAConnectivity component from the "**QuickOPC**" tab of the **Toolbox** to the form's design surface.

   Notice that three icons will appear below the form: One labeled "uaConnectivity1", the second labeled "pointBinder1", and the third labeled "bindingExtender1".

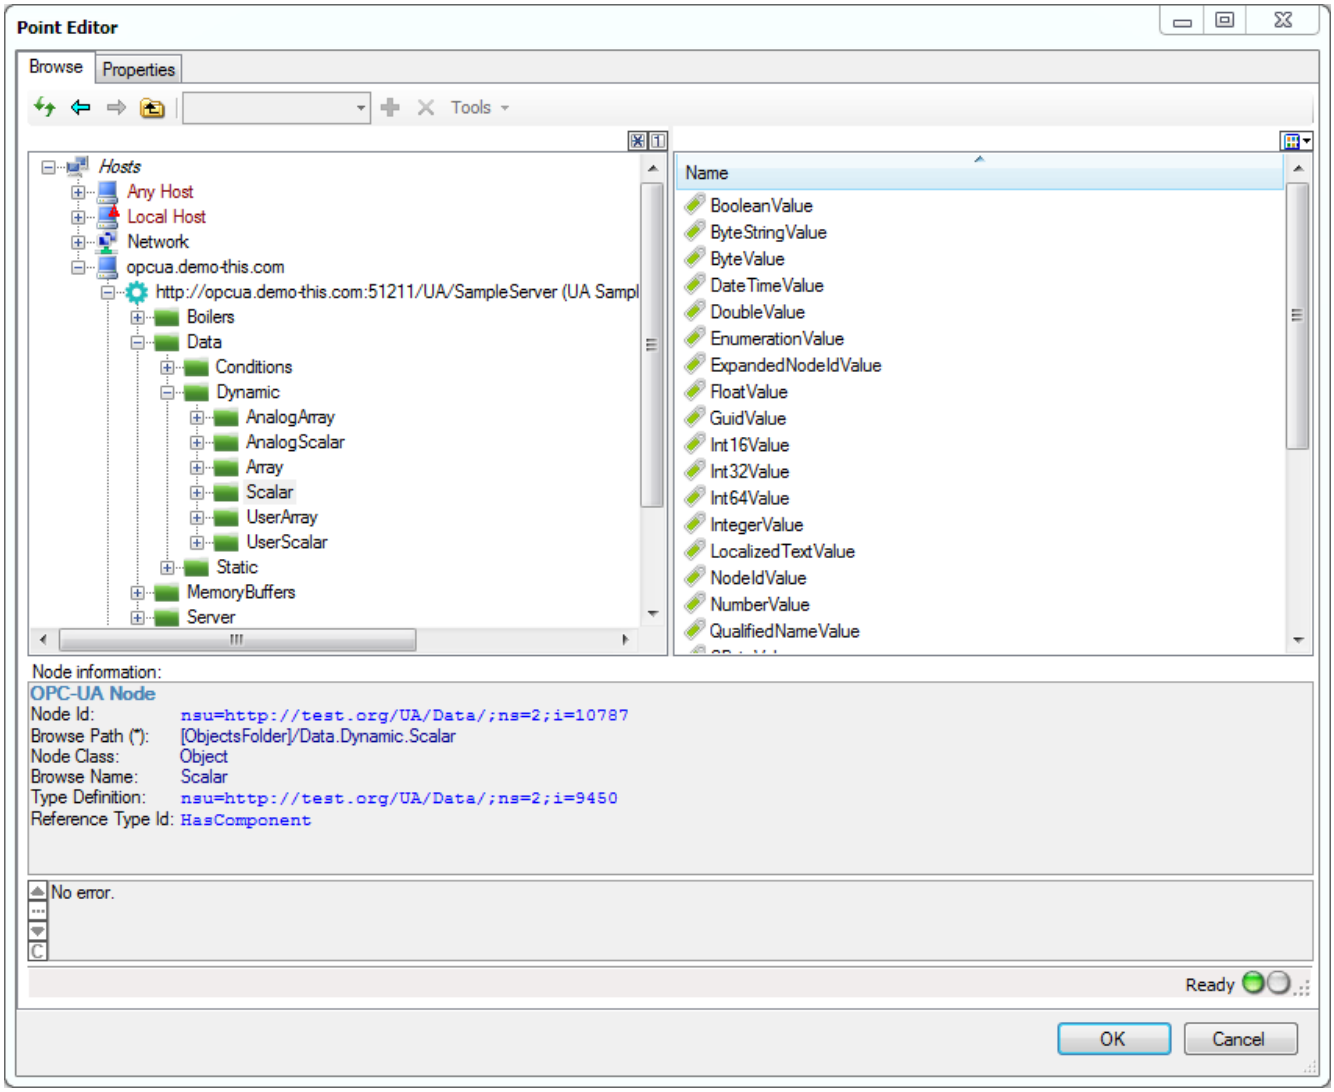
   If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

4. Drag a standard TextBox from the **Toolbox** to the form.
5. Right-click on the text box control on the form, and choose "Bind to Point" command.

   Alternatively, you can select the text box control first, and then choose the "Bind to Point" command in the Properties window; for this to work, however, the commands must be displayed in the **Properties** window.

   If you do not see these commands, display them by right-clicking in the **Properties** window, and checking "Commands" in the menu.

6. In the "Point Editor" dialog, select Hosts -> opcua.demo-this.com -> http:// opcua.demo-this.com:51211/UA/Sample Server (UA Sample Server) -> Data -> Dynamic -> Scalar -> Int32Value, and press OK.



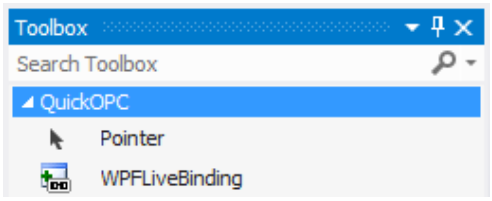
7. Build and run your application. You will see live OPC-UA data changing in the text box. It is also possible to verify the effects of live binding without building the application: On the **bindingExtender** component placed on the form, select the "Design Online" command. This will cause Visual Studio to perform the live binding immediately. Use the "Design Offline" command to revert back to normal mode.

3.2.2.2 Making a first OPC UA application using Live Binding in WPF

In this Getting Started procedure, we will create a WPF application in C# or Visual Basic that subscribes to OPC Data Access (OPC-DA) item and continuously displays it changes. The live binding model allows achieving this functionality by simply configuring the OPC Data Client components, without any manual coding.

1. Install OPC Data Client. Make sure that you have selected an installation choice that includes .NET development.
2. Start Microsoft Visual Studio, and create new Visual C# or Visual Basic project, selecting "WPF Application" template. **Make sure that in the upper part of the "New Project" dialog, the target framework is set to ".NET Framework 4.7" or later.**

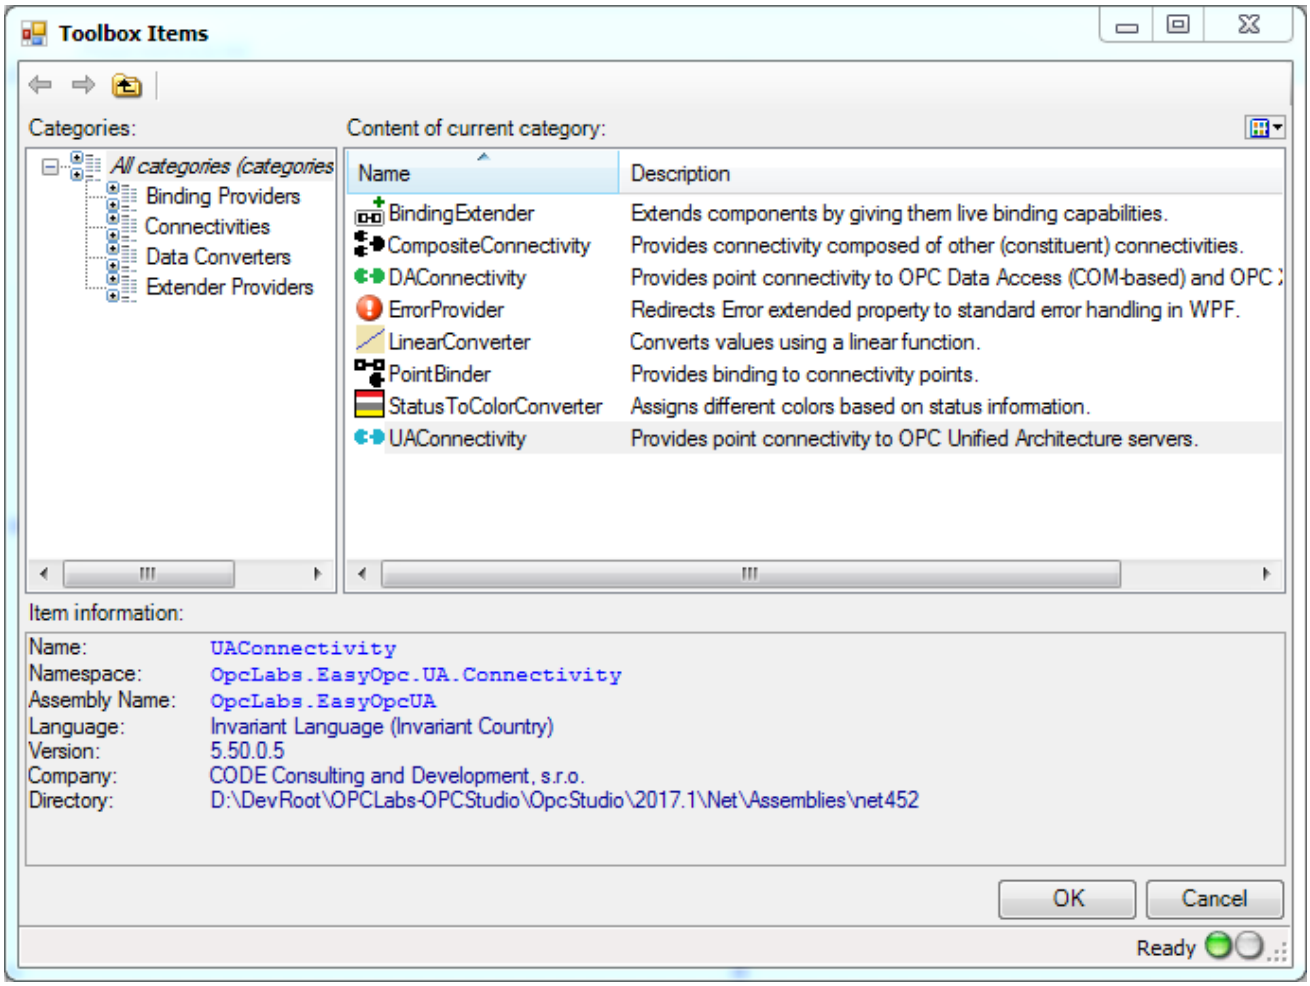
3. Drag the WPFLiveBinding component from the "**QuickOPC**" tab of the **Toolbox** to the window's design surface.



If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

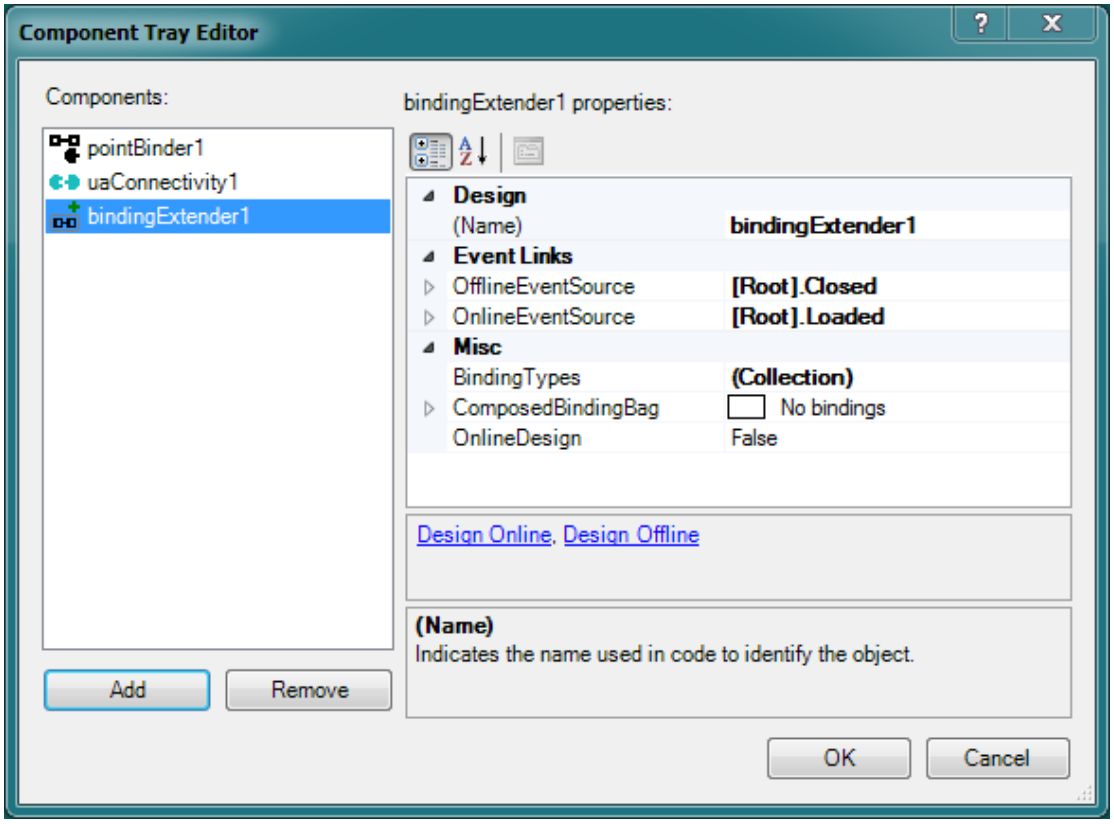
A **Component Tray Editor** dialog with an empty list of components will appear.

4. In the **Component Tray Editor** dialog, press the Add button. A **Toolbox Items** dialog will appear:



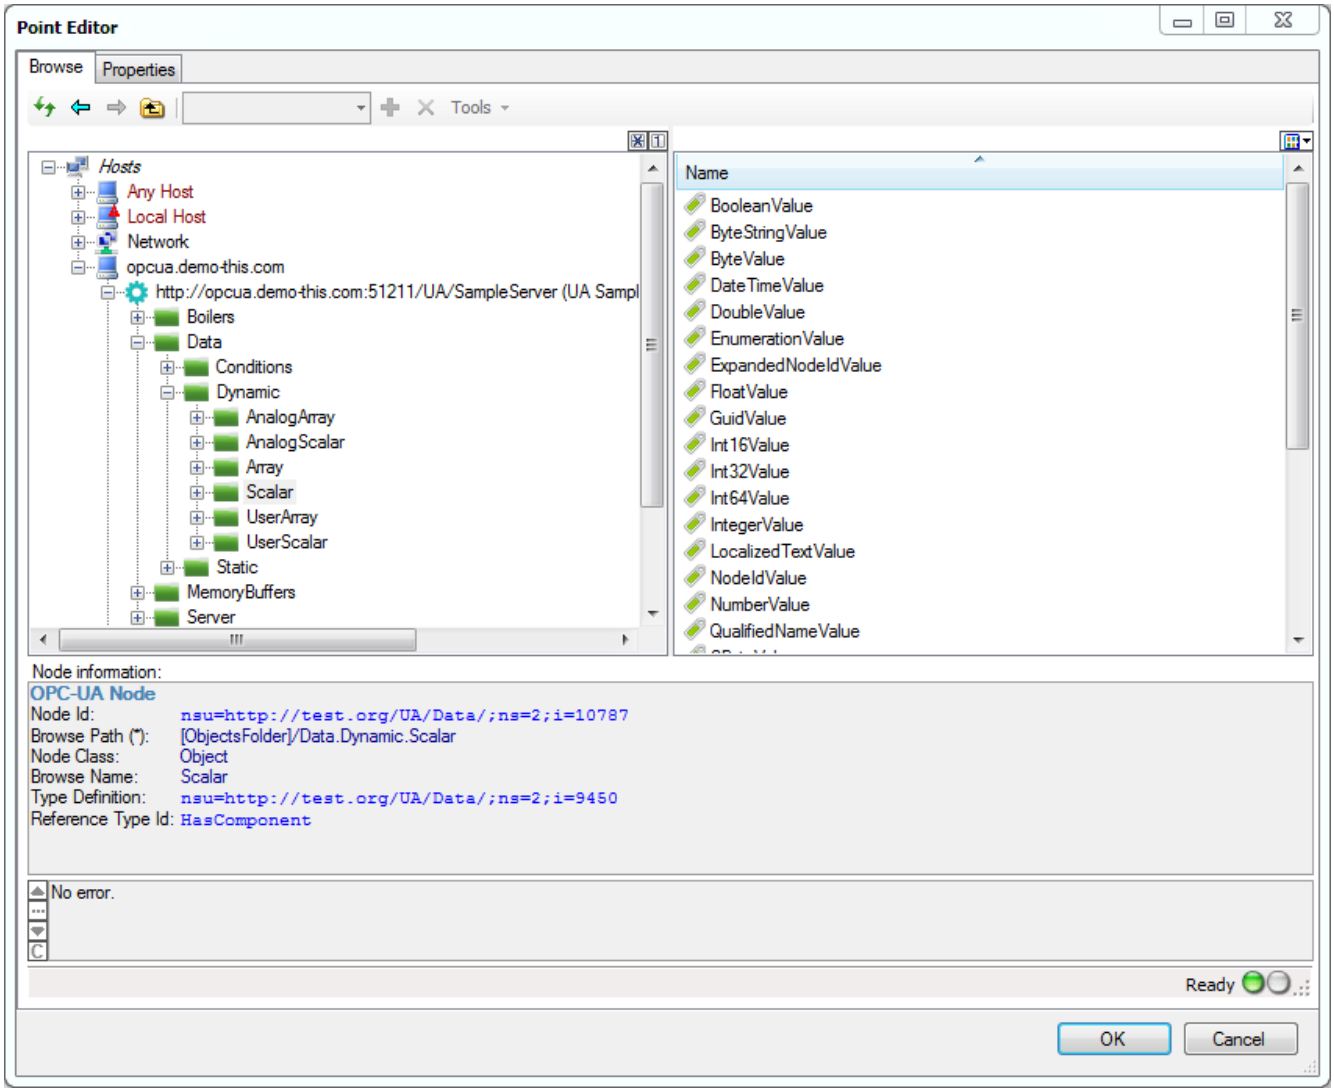
5. Select the UAConnectivity component from the **Content of current category list** of the **Toolbox Items** dialog, and press OK.

Notice that three entries will appear in the **Components** list in the **Component Tray Editor**: One labeled "uaConnectivity1", the second labeled "pointBinder1", and the third labeled "bindingExtender1":



6. In the **Component Tray Editor** dialog, press the OK button.
7. Drag a standard TextBox from the Visual Studio **Toolbox** to the designed window.
8. Right-click on the text box control on the designed window, and choose "Bind to Point" command.

   Alternatively, you can select the text box control first, and then expand the Live Binding category in the **Properties** windows, and next to the Live.Extensions property, choose the "Bind to Point" command there.
9. In the "Point Editor" dialog, select Hosts -> opcua.demo-this.com -> http:// opcua.demo-this.com:51211/UA/Sample Server (UA Sample Server) -> Data -> Dynamic -> Scalar -> Int32Value, and press OK.



10. Build and run your application. You will see live OPC-UA data changing in the text box. It is also possible to verify the effects of live binding without building the application: Right-click anywhere in the designed window area, and select the Online Design Live Binding command (this is an on-off command, with "on" state indicated by a check mark next to the menu item). Alternatively, expand the Live Binding category in the **Properties** window, and next to the Live.Extensions property, check the **Online Design Live Binding** box. This will cause Visual Studio to perform the live binding immediately. Use the same command to revert back to normal mode.

3.2.2.3 Making a first OPC UA application using traditional coding

> If you are targeting the .NET Standard development platform and not the .NET Framework, see **Getting Started under .NET Standard (Section 3.3)** instead.

If you are interested in OPC Data Client-UA, your task will most certainly involve reading data from an OPC server. Here are a few steps that illustrate how to achieve that, using Microsoft Visual Studio, and a simple Windows Forms application in C#. The steps are quite similar if you are using other tools or a different programming language.

We will create a form that will read a float value from the OPC server when loaded, and immediately display the formatted value in the text box on the form.

1. Install OPC Data Client. Make sure that you have selected an installation choice that includes .NET development.
2. Start Microsoft Visual Studio, and create new Visual C# project, selecting "Windows Forms Application" template. **Make sure that in the upper part of the "New Project" dialog, the target framework is set to ".NET Framework 4.7" or later.**
3. Instantiate the EasyUAClient component in the form: Drag the EasyUAClient component from the "**QuickOPC**" tab of the **Toolbox** to the form's design surface.

   An icon labeled "easyUAClient1" will appear below the form.

   If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

   Note: This is just shortcut way in Windows Forms to declaring and instantiating the component. In other environments, you can instantiate the component using the 'new' (C#) or 'New' (VB.NET) keyword, or any other way provided by the language or tool you are using.

4. Add a textbox to the form: Drag the TextBox component from the **Toolbox** to the form's design surface. The text box should appear on the form, and in the **Properties** window, you will see that it has been given a "textBox1" name.
5. Add handler for the Load event of the form: Select the form by clicking on its design surface (make sure that you do not have any other control selected). Then, in the **Properties** window, choose the "Events" view (orange lightning icon), and double-click the line with "Load" event (it is under Behavior group). A "Form1_Load" text in bold font will appear next to the event name, and a new event handler will be created for the Load event. The text editor will open for the code, and the caret will be placed into the Form1_Load method.
6. Add following code to the beginning of the **Form1.cs** file:

```
using OpcLabs.EasyOpc.UA;
```

7. Write the event handler implementation. Add the following code to the body of Form1_Load method:

```
textBox1.Text =
easyUAClient1.ReadValue("http://opcua.demo-this.com:51211/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=10853").ToString();
```

8. Build the project.
9. Run the application and observe the results. The text box on the form will be filled with a float value we have read from the OPC server, using a single code line!

If you are targeting an environment different from Windows Forms (such as console application, Web, or WPF), your steps will be similar. In place of Step 4, simply reference the OpcLabs.EasyOpcUA assembly, and create a new instance of **OpcLabs.EasyOpc.UA.EasyUAClient** object.

3.2.2.4 Where do I go from here?

You now have a basic idea of how to use the OPC Data Client-UA. There are many additional resources that you can use to gain additional knowledge about the product. Here are some of them:

- Play with the Demo application (accessible from the Start menu or the Launcher application) and explore the various functionalities that the product provides.
- Read the User's Guide.
- Study the Reference documentation.
- Review the additional examples and tools included with the product.

3.3 Getting Started under .NET Standard

This section of the documentation consists of following parts:

- **Getting Started under .NET Standard using .NET Core CLI Tools (Section 3.3.1)**,
- **Getting Started under .NET Standard using IDE (Section 3.3.2)**, and
- **Getting Started under .NET Standard using Visual Studio Code (Section 3.3.3)**.

Depending on your .NET runtime and development tool, please refer to the corresponding part.

3.3.1 Getting Started under .NET Standard using .NET Core CLI Tools

In this Getting Started, we will create a console application running in .NET Core that will read a value from an OPC server, and display the value on the console.

In This Topic

Prerequisites

- Supported operating system: **Linux** or **Windows**.
- **.NET Core SDK 2.1.103** (or possibly higher version): Linux instructions, Windows instructions.
- A text editor or code editor of your choice.
- Internet connection with access to www.nuget.org (for downloading NuGet packages) and www.opclabs.com (for connection to the public OPC UA server).

If you want to verify the version of .NET Core on your computer, use the ***dotnet --info*** command in the command prompt, and look for the **Version** field under **"Microsoft .NET Core Shared Framework Host"**, or (in newer versions) under **".NET Core runtimes installed:"** in the generated output. Do not use ***dotnet --version***, because this command only returns the version of the .NET Core command-line tools.

Console Application to Read Value from OPC Unified Architecture

Server

1. Open a command prompt.
2. Create a folder named **Hello** and navigate to the folder.
3. Type the following: ***dotnet new console***. This command creates a project file (**Hello.csproj**) and a main program file (**Program.cs**).
4. Type the following: ***dotnet add package OpcLabs.QuickOpc***. This command adds OPC Data Client package reference to the project file.

   > The above command actually adds a reference to the package corresponding always to the very latest OPC Data Client version. If you want to be sure that you referencing a package for OPC Data Client 2020.2, use ***dotnet add package OpcLabs.QuickOpc --version 5.58*** command instead.

5. Using a text editor, add following code to the beginning of the **Program.cs** file:

```
using OpcLabs.EasyOpc.UA;
```

6. In **Program.cs**, replace the body of the Main method by following code:

```
var client = new EasyUAClient();
object value = client.ReadValue(
    "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
    "nsu=http://test.org/UA/Data/;i=10853");
Console.WriteLine(value);
```

7. Save the changes to **Program.cs**.
8. In the command prompt, type ***dotnet run***. This will build and launch the program. The value will be read from the OPC server and displayed on the console.

Console Application to Read Value from OPC XML-DA Server

1. Open a command prompt.
2. Create a folder named **HelloXml** and navigate to the folder.
3. Type the following: ***dotnet new console***. This command creates a project file (**HelloXml.csproj**) and a main program file (**Program.cs**).
4. Type the following: ***dotnet add package OpcLabs.QuickOpc***. This command adds OPC Data Client package reference to the project file.

   > The above command actually adds a reference to the package corresponding always to the very latest OPC Data Client version. If you want to be sure that you referencing a package for OPC Data Client 2020.2, use ***dotnet add package OpcLabs.QuickOpc --version 5.58*** command instead.

5. Using a text editor, add following code to the beginning of the **Program.cs** file:

```
using OpcLabs.EasyOpc.DataAccess;
```

6. In **Program.cs**, replace the body of the Main method by following code:

```
var client = new EasyDAClient();
object value = client.ReadItemValue(
    "http://opcxml.demo-this.com/XmlDaSampleServer/Service.asmx",
    "Dynamic/Analog Types/Double");
Console.WriteLine(value);
```

7. Save the changes to **Program.cs**.

8. In the command prompt, type ***dotnet run***. This will build and launch the program. The value will be read from the OPC server and displayed on the console.

3.3.2 Getting Started under .NET Standard using IDE

In this Getting Started, we will create a console application running in .NET Core that will read a value from an OPC server, and display the value on the console.

In This Topic

Prerequisites

- Supported operating system: **Linux** or **Windows**.
- **.NET Core SDK 2.1.103** (or possibly higher version): Linux instructions, Windows instructions.
- **Visual Studio**, or **JetBrains Rider**.
- Internet connection with access to www.nuget.org (for downloading NuGet packages) and www.opclabs.com (for connection to the public OPC UA server).

If you want to verify the version of .NET Core on your computer, use the ***dotnet --info*** command in the command prompt, and look for the **Version** field under **"Microsoft .NET Core Shared Framework Host"**, or (in newer versions) under **".NET Core runtimes installed:"** in the generated output. Do not use ***dotnet --version***, because this command only returns the version of the .NET Core command-line tools.

Console Application to Read Value from OPC Unified Architecture Server

1. Start the IDE (Integrated Development Environment) of your choice.

2. In this step, we will create a new .NET Core console application project.

   If you are using Visual Studio, select File -> New -> Project from the menu. In the **New Project** dialog, navigate to Installed -> Visual C# -> .NET Core, and select Console App (.NET Core). Press the OK button.

   If you are using JetBrains Rider, select **New Solution** on the **Welcome to JetBrains Rider** screen. In the **New Solution** dialog, select .NET Core -> Console Application. Verify the **Language** or change it to C#. Press the Create button.

3. In this step, we will add a reference to the **OpcLabs.QuickOpc** NuGet package.

   If you are using Visual Studio, switch to the **Solution Explorer** window, right-click on the project node

(ConsoleApp*n*), and select Manage NuGet Packages... command. In the **NuGet: *project*** window, switch to the **Browse** tab, and type ***OpcLabs.QuickOpc*** into the search box. Select the OpcLabs.QuickOpc package in the package list in the left pane of the window. In the right pane of the window, verify or change the package version next to the **Version** label. The version should be "Latest stable 5.58.*build*" (where *build* is a build number). Press the Install button.

If you are using JetBrains Rider, switch to the **NuGet** window; if it is not visible, use View -> Tool Windows -> NuGet (***Alt+7***) command from the menu. In the **NuGet** window, switch to the **Packages** tab, and type ***OpcLabs.QuickOpc*** into the search box. Select the OpcLabs.QuickOpc package under **Available Packages** list in the left pane of the window. In the right pane of the window, verify or change the package version next to the **Version** label. The version should be "5.58.*build*" (where *build* is a build number). Press the green + button next to the name of your project. Press the Yes button when asked to confirm the installation of the package.

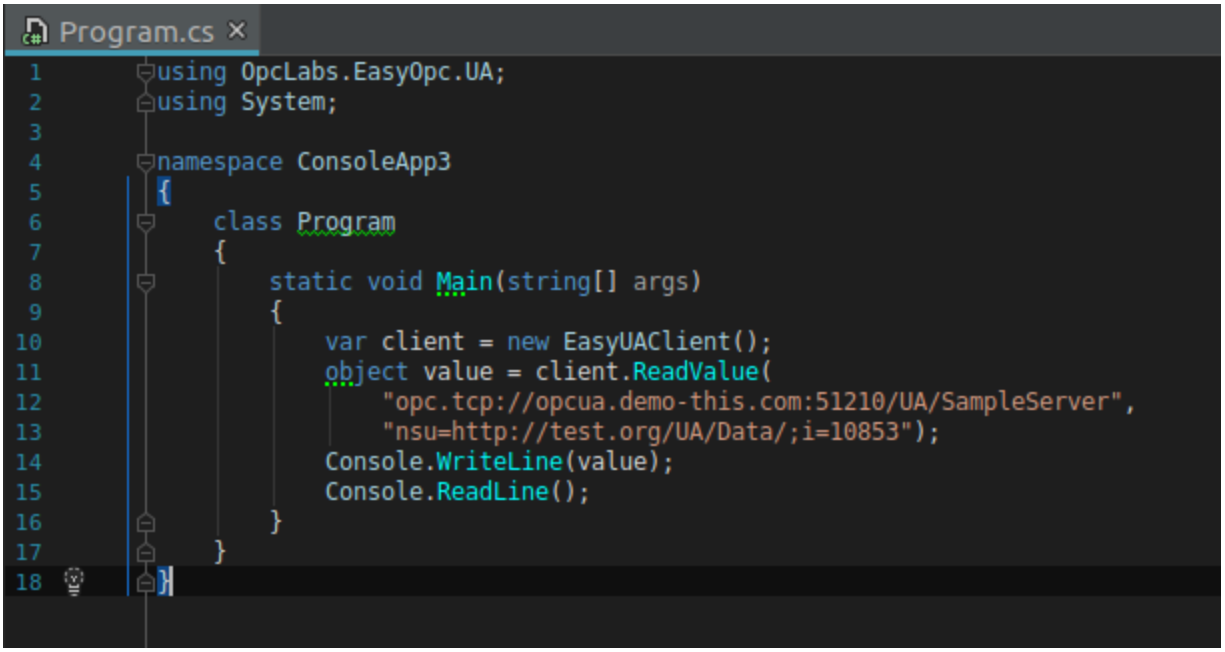
4. Open the **Program.cs** file, and add following code to the beginning of the file:

```
using OpcLabs.EasyOpc.UA;
```

5. In **Program.cs**, replace the body of the Main method by following code:

```
var client = new EasyUAClient();
object value = client.ReadValue(
    "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
    "nsu=http://test.org/UA/Data/;i=10853");
Console.WriteLine(value);
Console.ReadLine();
```

The program may now look like this in the IDE:



6. If you are using Visual Studio, select Debug -> Start Debugging (***F5***) from the menu, or press the corresponding button on the toolbar.

If you are using JetBrains Rider, select Run -> Debug 'Default' (***F5***), or press the corresponding button on the toolbar. When the **Edit configuration** dialog appears, press the Debug button.

This will build and launch the program. The value will be read from the OPC server and displayed on the console.

Press ***Enter*** to exit the program.

Console Application to Read Value from OPC XML-DA Server

1. Start the IDE (Integrated Development Environment) of your choice.

2. In this step, we will create a new .NET Core console application project.

   If you are using Visual Studio, select File -> New -> Project from the menu. In the **New Project** dialog, navigate to Installed -> Visual C# -> .NET Core, and select Console App (.NET Core). Press the OK button.

   If you are using JetBrains Rider, select **New Solution** on the **Welcome to JetBrains Rider** screen. In the **New Solution** dialog, select .NET Core -> Console Application. Verify the **Language** or change it to C#. Press the Create button.

3. In this step, we will add a reference to the **OpcLabs.QuickOpc** NuGet package.

   If you are using Visual Studio, switch to the **Solution Explorer** window, right-click on the project node (ConsoleApp*n*), and select Manage NuGet Packages... command. In the **NuGet: *project*** window, switch to the **Browse** tab, and type ***OpcLabs.QuickOpc*** into the search box. Select the OpcLabs.QuickOpc package in the package list in the left pane of the window. In the right pane of the window, verify or change the package version next to the **Version** label. The version should be "Latest stable 5.58.*build*" (where *build* is a build number). Press the Install button.

   If you are using JetBrains Rider, switch to the **NuGet** window; if it is not visible, use View -> Tool Windows -> NuGet (***Alt+7***) command from the menu. In the **NuGet** window, switch to the **Packages** tab, and type ***OpcLabs.QuickOpc*** into the search box. Select the OpcLabs.QuickOpc package under **Available Packages** list in the left pane of the window. In the right pane of the window, verify or change the package version next to the **Version** label. The version should be "5.58.*build*" (where *build* is a build number). Press the green + button next to the name of your project. Press the Yes button when asked to confirm the installation of the package.

4. Open the **Program.cs** file, and add following code to the beginning of the file:

   ```
   using OpcLabs.EasyOpc.DataAccess;
   ```

5. In **Program.cs**, replace the body of the Main method by following code:

   ```
   var client = new EasyDAClient();
   object value = client.ReadItemValue(
       "http://opcxml.demo-this.com/XmlDaSampleServer/Service.asmx",
       "Dynamic/Analog Types/Double");
   Console.WriteLine(value);
   ```

6. If you are using Visual Studio, select Debug -> Start Debugging (***F5***) from the menu, or press the corresponding button on the toolbar.

   If you are using JetBrains Rider, select Run -> Debug 'Default' (***F5***), or press the corresponding button on the toolbar. When the **Edit configuration** dialog appears, press the Debug button.

   This will build and launch the program. The value will be read from the OPC server and displayed on the console. Press ***Enter*** to exit the program.

3.3.3 Getting Started under .NET Standard using Visual Studio Code

⚠ This article is for development with Visual Studio Code, a multi-platform source code editor developed by Microsoft. For development with "full" Visual Studio (Windows-only) IDE, see **Getting Started under .NET Standard using IDE (Section 3.3.2)**.

In This Topic

Prerequisites

- Supported operating system: **Linux** or **Windows**.
- **.NET Core SDK 2.1.103** (or possibly higher version): Linux instructions, Windows instructions.
- **Visual Studio Code** (https://code.visualstudio.com/).
- **C# extension for Visual Studio Code**.
- Internet connection, including access to www.opclabs.com (for connection to the public OPC UA server)..

If you want to verify the version of .NET Core on your computer, use the ***dotnet --info*** command in the command prompt, and look for the **Version** field under **".NET Core Shared Framework Host"**, or (in newer versions) under **".NET Core runtimes installed:"** in the generated output. Do not use ***dotnet --version***, because this command only returns the version of the .NET Core command-line tools.

Console Application to Read Value from OPC Unified Architecture Server

1. Open a command prompt.
2. Create a folder named **Hello** and navigate to the folder.
3. Type the following: ***dotnet new console***. This command creates a project file (**Hello.csproj**) and a main program file (**Program.cs**).
4. Type the following: ***dotnet add package OpcLabs.QuickOpc***. This command adds OPC Data Client package reference to the project file.

   The above command actually adds a reference to the package corresponding always to the very latest OPC Data Client version. If you want to be sure that you referencing a package for OPC Data Client 2020.2, use ***dotnet add package OpcLabs.QuickOpc --version 5.58*** command instead.

5. Type the following: ***code .*** (note the dot '.' as a parameter to the command.) Visual Studio Code starts and its window opens.
6. At this point, you might be asked **"Required assets to build and debug are missing from 'vscode'. Add them?"**. If so, press the Yes button in the popup window.
7. A notification will appear **"There are unresolved dependencies from 'Hello.csproj'. Please execute the restore**

command to continue.". Press the Restore button in the popup window.

8. In the **Explorer** window, click on the Program.cs file. The file opens in the code editor.
9. Add following code to the beginning of the **Program.cs** file:

```
using OpcLabs.EasyOpc.UA;
```

10. In **Program.cs**, replace the body of the Main method by following code:

```
var client = new EasyUAClient();
object value = client.ReadValue(
    "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
    "nsu=http://test.org/UA/Data/;i=10853");
Console.WriteLine(value);
```

11. Select Debug -> Start Debugging (***F5***) from the menu, or press the corresponding button on the toolbar.

    This will build and launch the program. The value will be read from the OPC server and displayed in the **Debug Console** window.

Console Application to Read Value from OPC XML-DA Server

1. Open a command prompt.
2. Create a folder named **HelloXml** and navigate to the folder.
3. Type the following: ***dotnet new console***. This command creates a project file (**HelloXml.csproj**) and a main program file (**Program.cs**).
4. Type the following: ***dotnet add package OpcLabs.QuickOpc***. This command adds OPC Data Client package reference to the project file.

   > The above command actually adds a reference to the package corresponding always to the very latest OPC Data Client version. If you want to be sure that you referencing a package for OPC Data Client 2020.2, use ***dotnet add package OpcLabs.QuickOpc --version 5.58*** command instead.

5. Type the following: ***code .*** (note the dot '.' as a parameter to the command.) Visual Studio Code starts and its window opens.
6. At this point, you might be asked **"Required assets to build and debug are missing from 'vscode'. Add them?"**. If so, press the Yes button in the popup window.
7. A notification will appear **"There are unresolved dependencies from 'Hello.csproj'. Please execute the restore command to continue."**. Press the Restore button in the popup window.
8. In the **Explorer** window, click on the Program.cs file. The file opens in the code editor.
9. Add following code to the beginning of the **Program.cs** file:

```
using OpcLabs.EasyOpc.DataAccess;
```

10. In **Program.cs**, replace the body of the Main method by following code:

```
var client = new EasyDAClient();
object value = client.ReadItemValue(
    "http://opcxml.demo-this.com/XmlDaSampleServer/Service.asmx",
    "Dynamic/Analog Types/Double");
Console.WriteLine(value);
```

11. Select Debug -> Start Debugging (***F5***) from the menu, or press the corresponding button on the toolbar.

    This will build and launch the program. The value will be read from the OPC server and displayed in the **Debug Console** window.

3.4 Getting Started with OPC UA PubSub under .NET

In this Getting Started, we will use Visual Studio (on Windows) create a console application running that will subscribe to datasets produced by an OPC UA demo publisher, and display the received data on the console. You can target .NET Framework or .NET Core.

Note: The same code will work under Linux as well, but the steps to create the program are different - yo uwill need to use .NET Core CLI Tools, or other IDE such as JetBrains Rider.

In This Topic

1. Start Visual Studio.

2. In this step, we will create a new .NET console application project.

   Select File -> New -> Project from the menu. The dialog(s) that follow differ in different versions of Visual Studio, so we wil just describe the intent here: Select Console App (.NET Core) or Console App (.NET Framework), in C#. If given a choice of framework, make sure you select one of the supported **.NET Runtimes (Section 2.4.1)**. Finalize the dialog, creating the project.

   If you were not given a choice of framework, right-click on the project node in the **Solution Explorer** window, select Properties, and check the **Target Framework** setting.

3. In this step, we will add a reference to the **OpcLabs.QuickOpc** NuGet package.

   Switch to the **Solution Explorer** window, right-click on the project node (ConsoleApp*n*), and select Manage NuGet Packages... command. In the **NuGet: *project*** window, switch to the **Browse** tab, and type ***OpcLabs.QuickOpc*** into the search box. Select the OpcLabs.QuickOpc package in the package list in the left pane of the window. In the right pane of the window, verify or change the package version next to the **Version** label. The version should be "Latest stable 5.58.*build*" (where *build* is a build number). Press the Install button.

   > If you are developing for .NET Framework (not .NET Core) and have installed OPC Data Client using its full **Setup** program, you can instead use assembly references to the OPC Data Client assemblies installed locally. To do so, switch to the **Solution Explorer** window, right-click on the project node (ConsoleApp*n*), and select Add Reference... command. In the **Reference Manager** dialog, select Assemblies -> Extensions, check the boxes next to "OPC Labs Base Library Core" and "OPC Labs EasyOPC-UA Library", and press OK.

4. Open the **Program.cs** file, and add following code to the beginning of the file:

   ```
   using OpcLabs.EasyOpc.UA.PubSub;
   ```

5. In **Program.cs**, replace the body of the Main method by following code (use Copy&Paste from here):

   ```
   var subscriber = new EasyUASubscriber();
   subscriber.SubscribeDataSet("opc.udp://239.0.0.1", (_, eventArgs) =>
   {
   ```

```
        if (eventArgs.Succeeded)
        {
            if (!(eventArgs.DataSetData is null))
            {
                Console.WriteLine();
                Console.WriteLine($"Dataset data: {eventArgs.DataSetData}");
                foreach (var pair in eventArgs.DataSetData.FieldDataDictionary)
                    Console.WriteLine(pair);
            }
        }
        else
        {
            Console.WriteLine();
            Console.WriteLine($"*** Failure: {eventArgs.ErrorMessageBrief}");
        }
    });
    Console.ReadLine();
    subscriber.UnsubscribeAllDataSets();
```

6. Visit Tool Downloads page and download and unpack **OPC UA Demo Publisher** (the easiest to work with is Self-extracting EXE, but other format will do as well). In accordance with instructions on the UADemoPublisher Basics page, run the OPC UA Demo Publisher without further parameters.

   > If you have installed OPC Data Client using its full **Setup** program, you can bypass the tool download and installation described above, and simply run Tools -> OPC UA Demo Publisher from the **Launcher** application, or Windows **Start** menu.

   The OPC UA Demo Publisher will start broadcasting messages that our application will receive. You will see a progress indication (message counts) in its console window. You can run the OPC UA Demo Publisher either on the same computer where you are developing the application, or on a different computer on the same local network (IP subnet).

7. Select Debug -> Start Debugging (***F5***) from the menu, or press the corresponding button on the toolbar.

   This will build and launch the program. The datasets from the publisher will be received by your subscriber application, and displayed on the console. Press ***Enter*** to exit the program.

Troubleshooting

See OPC UA PubSub Common Traps And Pitfalls if things do not work as expected - and specifically, if your subscriber application is not receiving anything and is giving you timeout errors.

Probably the most common issue is the necessity to properly specify a (non-default) network interface. For the **OPC UA Demo Publisher**, this is done using the **--ConnectionNetworkInterface** (**-cni**) option. For a suggestion about how this is done in your application, see e.g. the code comments in **Examples - OPC UA PubSub - Callback using a lambda (Section 13.2.11.1)**.

3.5 Getting Started under COM

This section of the documentation consists of following parts:

- **Getting Started with OPC Classic under COM (Section 3.5.2)**, and
- **Getting Started with OPC UA under COM (Section 3.5.2)**.

Depending on whether you develop OPC "Classic" or OPC Unified Architecture applications under the COM platform, please refer to the corresponding part.

3.5.1 Getting Started with OPC Classic under COM

Start here: **Making a first COM application in VB6 (Section 3.5.1.1)**.

3.5.1.1 Making a first COM application in VB6

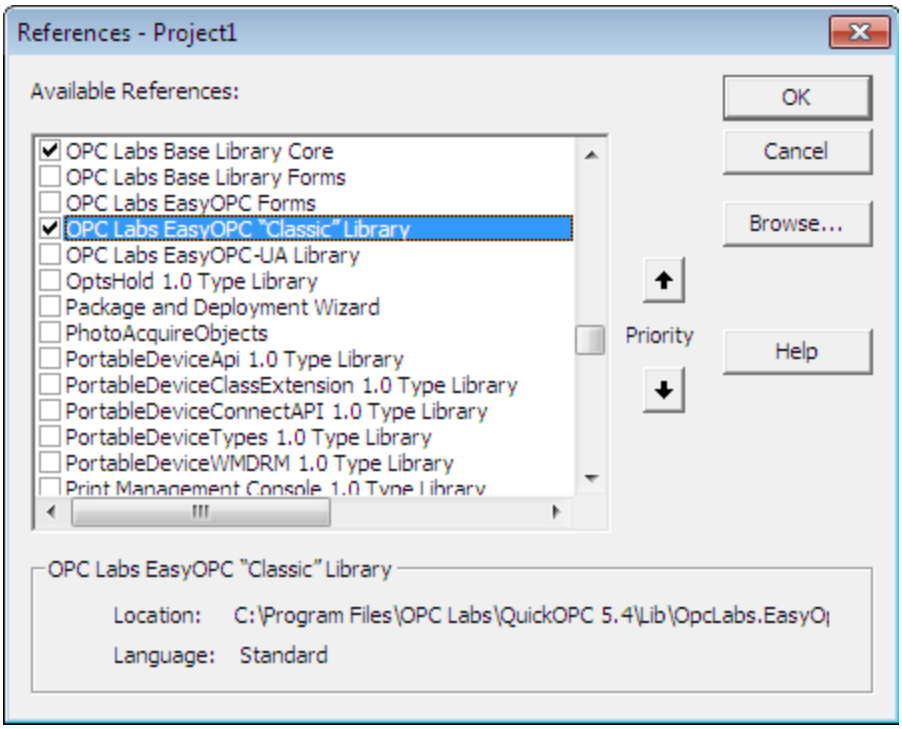
If you are interested in OPC Data Client-COM, your task will most certainly involve reading data from an OPC server. Here are a few steps that illustrate how to achieve that, using Visual Basic 6.0. The steps are similar if you are using other tools or a different programming language.

In This Topic

A Form to Read Value from OPC Data Access Server

We will create a form that will read a float value from the OPC server when loaded, and immediately display the formatted value in the text box on the form.

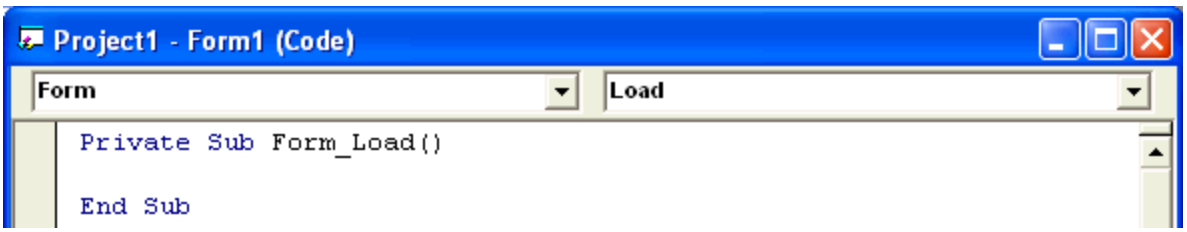
1. Install OPC Data Client. Make sure that you have selected an installation choice that includes COM development.
2. Start Visual Basic 6.0, and create new project, selecting "Standard EXE" project type.
3. Reference the EasyOPC-DA component: Select Project -> References from the menu, and look for "OPC Labs EasyOPC "Classic" Type Library" in the list of available references. Check the box next to it, and press OK.



Note: If some of the OPC Data Client the type libraries are not shown in the References list, use the Browse... button to locate and select them manually. The type libraries are installed under the **SDK\lib** subdirectory under the OPC Data Client installation folder. Sometimes, simply restarting the Visual Basic 6.0 helps.

4. Place a Text Box onto the form's surface. Keep the name Text1.

5. Add handler for the Load event of the form: Switch to Code View, and select the Form object and then its Load member. Visual Basic will add the handler's skeleton as follows:



6. Write the event handler implementation. Add the following code to the body of Form_Load method:

```
' Create EasyOPC-DA component
Dim EasyDAClient As New EasyDAClient

' Read item value and display it
Me.Text1 = EasyDAClient.ReadItemValue("", "OPCLabs.KitServer.2", "Demo.Single")
```

7. Build and run the application by selecting Run -> Start from the menu, and observe the results. The text box on the form will be filled with a float value we have read from the OPC server.

Notes

If you are using a tool that does not have a referencing mechanism similar to Visual basic, you may need to create the EasyOPC-DA component directly. To do so, use the tool's mechanism to create instance of a COM object, passing it a ProgID string "OpcLabs.EasyOpc.DataAccess.EasyDAClient".

3.5.1.2 Where do I go from here?

You now have a basic idea of how to use the OPC Data Client-COM. There are many additional resources that you can use to gain additional knowledge about the product. Here are some of them:

- Play with the Demo application (accessible from the Start menu or the Launcher application) and try obtaining data from the included Simulation OPC server, but also from other OPC servers on your computer or your network.
- Read the User's Guide.
- Study the Reference documentation.
- Review the additional examples and tools included with the product.

3.5.2 Getting Started with OPC UA under COM

Start here: **Making a first UA application in VB6 (Section 3.5.2.1)**.

3.5.2.1 Making a first UA application in VB6

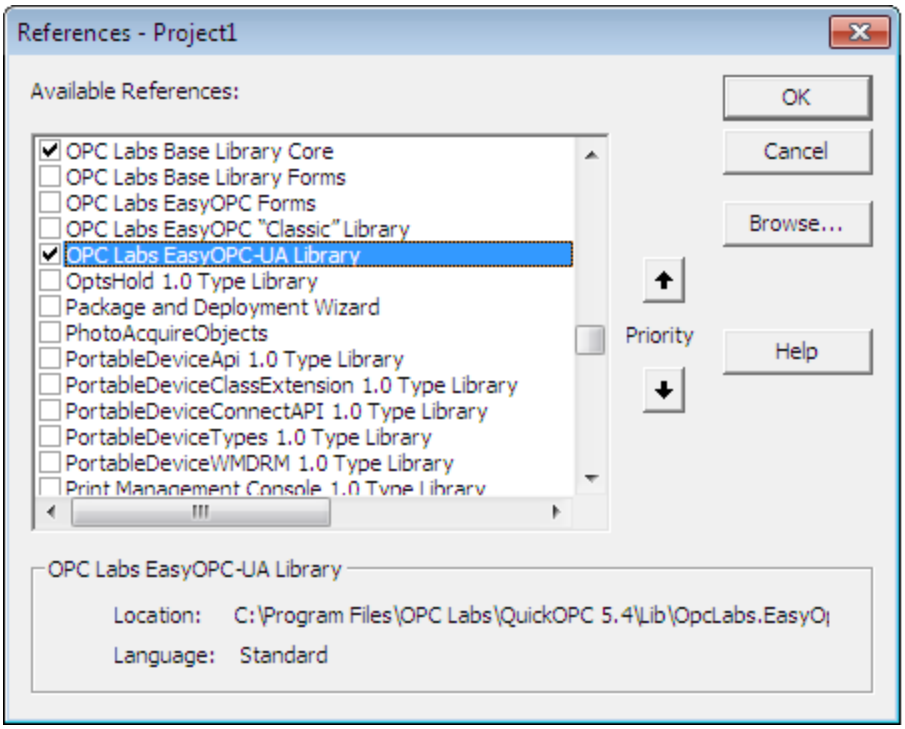
If you are interested in OPC Data Client-UA, your task will most certainly involve reading data from an OPC UA server. Here are a few steps that illustrate how to achieve that, using Visual Basic 6.0. The steps are similar if you are using other tools or a different programming language.

In This Topic

A Form to Read Value from OPC Unified Architecture Server

We will create a form that will read a float value from the OPC UA server when loaded, and immediately display the formatted value in the text box on the form.

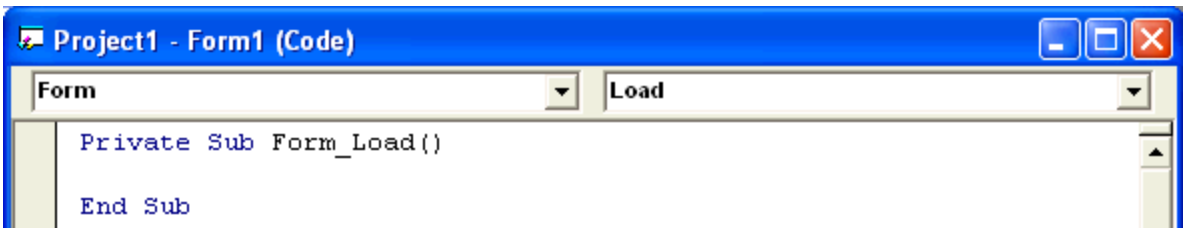
1. Install OPC Data Client. Make sure that you have selected an installation choice that includes COM development.
2. Start Visual Basic 6.0, and create new project, selecting "Standard EXE" project type.
3. Reference the EasyOPC component: Select Project -> References from the menu, and look for "OPC Labs EasyOPC-UA Type Library" in the list of available references. Check the box next to it, and press OK.



Note: If some of the OPC Data Client the type libraries are not shown in the References list, use the Browse... button to locate and select them manually. The type libraries are installed under the **SDK\lib** subdirectory under the OPC Data Client installation folder. Sometimes, simply restarting the Visual Basic 6.0 helps.

4. Place a Text Box onto the form's surface. Keep the name Text1.

5. Add handler for the Load event of the form: Switch to Code View, and select the Form object and then its Load member. Visual Basic will add the handler's skeleton as follows:



6. Write the event handler implementation. Add the following code to the body of Form_Load method:

```
' Create EasyOPC-UA component
Dim Client As New EasyUAClient

' Read node value and display it
Me.Text1 = Client.ReadValue("http://opcua.demo-this.com:51211/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=10853")
```

7. Build and run the application by selecting Run -> Start from the menu, and observe the results. The text box on the form will be filled with a float value we have read from the OPC UA server.

Notes

If you are using a tool that does not have a referencing mechanism similar to Visual basic, you may need to create the EasyOPC-UA component directly. To do so, use the tool's mechanism to create instance of a COM object, passing it a ProgID string "OpcLabs.EasyOpc.UA.EasyUAClient".

3.5.2.2 Where do I go from here?

You now have a basic idea of how to use the OPC Data Client-COM. There are many additional resources that you can use to gain additional knowledge about the product. Here are some of them:

- Play with the Demo application (accessible from the Start menu) and explore the various functionalities that the product provides.
- Read the User's Guide.
- Study the Reference documentation.
- Review the additional examples and tools included with the product.

4 Fundamentals

This chapter describes the fundamental concepts used within OPC Data Client component. Please read it through, as the knowledge of Fundamentals is assumed in later parts of this document.

4.1 Product Parts

4.1.1 Assemblies

At the core of OPC Data Client.NET, there are .NET assemblies that contain reusable library code. You reference these assemblies from the code of your application, and by instantiating objects from those assemblies and calling methods on them, you gain the OPC functionality.

For easy recognition among other assemblies when used in a larger context, all our assemblies start with "OpcLabs" prefix.

Assembly List

Following assemblies form the main part of OPC Data Client.NET:

Assembly Name or File	Title	Description	Strong-named	Present locally - for .NET Framework	Present in NuGet package - .NET Framework	Present in NuGet package - .NET Standard
App_Web_OpcLabs.EasyOpcClassicRaw.amd64	EasyOPC "Classic" Raw Library	Used internally. Low-level OPC "Classic" code, a mixed mode assembly, for 64-bit processes (x64 architecture).	yes	✓	✓	×
App_Web_OpcLabs.EasyOpcClassicRaw.x86	EasyOPC "Classic" Raw Library	Used internally. Low-level OPC "Classic" code, a mixed	yes	✓	✓	×

		mode assembly, for 32-bit processes (x86 architecture).				
OpcLabs.BaseLib	OPC Labs Base Library Core	Supporting code.	yes	✓	✓	✓
OpcLabs.BaseLibForms	OPC Labs Base Library Forms	Contains fundamental and common classes for Windows Forms.	yes	✓	✓	×
OpcLabs.BaseLibPresentation	OPC Labs Base Library Presentation	Contains fundamental and common classes for Windows Presentation Foundation (WPF).	yes	×	✓	×
OpcLabs.EasyOpcClassic	EasyOPC "Classic" Library	Contains classes that facilitate easy work with various OPC specifications, such as OPC Data Access, OPC XML-DA, and OPC Alarms and Events.	yes	✓	✓	✓
OpcLabs.EasyOpcForms	EasyOPC Forms	Contains classes that facilitate easy work with OPC (both "Classic" and Unified Architecture) from Windows Forms applications.	yes	✓	✓	×

OpcLabs.EasyOpcUA	EasyOPC-UA Library	Contains classes that facilitate easy work with OPC Unified Architecture.	yes	✓	✓	✓

The name of the physical file that contains the assembly is always same as the name of the assembly, with a file extension ".dll".

When targeting .NET Framework, the OPC Unified Architecture components are based on version 1.03 of the .NET Stack from OPC Foundation. When targeting .NET Standard, the OPC Unified Architecture components are based on version 1.04 of the .NET Stack from OPC Foundation.

For the curious, OPC Data Client has been developed in Microsoft Visual Studio 2019. The layers that directly use COM (such as the OpcLabs.EasyOpcClassic assembly) are written in managed C++ (C++/CLI). More precisely, they are mixed mode assemblies, where the bulk of the code is in MSIL instructions, with a few exceptions where necessary. All other parts are written in pure C#.

Additional packages

OPC Data Client also includes packages (sets of assemblies) that are only used in specific circumstances, as documented. They are available as NuGet packages (from www.nuget.org , for use in .NET Standard projects), or as ZIP packages (links to corresponding ZIP file downloads are installed with the product and reachable through Redistributables item in the Start menu or the Launcher program).

The additional packages include e.g.:

- MQTT communication packages
- OPC UA PubSub JSON mapping package
- OpcLabs.Pcap communication package

The additional packages may have their own licensing requirements, different from the core OPC Data Client.

Assemblies for .NET Framework

The assembly files are installed into a subdirectory called **Assemblies\net47** under the installation directory of the product.

OPC Data Client components were consciously written to target Microsoft .NET Framework 4.7, i.e. they do not depend on features available only in the later version of the framework. As such, you can use the components in applications targeting version 4.7, 4.7.1, 4.7.2 or 4.8 of the Microsoft .NET Framework.

There is also a **Design** subfolder under the **Assemblies** folder, which contains additional OPC Data Client assemblies that are used during design time only. These assemblies are never referenced or used in run-time by your projects.

For development purposes, the assemblies under the **Design** subfolder are installed into the GAC (Global Assembly Cache) by the setup program. Other (runtime) assemblies are not installed into the GAC by default (the installation program can do it if you select the custom installation, it will then offer you this option near the end of the installation). You do not have to install assemblies into the GAC on the runtime computers, though. We recommend against installing the runtime assemblies into the GAC, unless you have a compelling reason for it.

The somewhat strange naming of certain assemblies, with names starting with "**App_Web_**" prefix, is needed for proper mixed-mode assembly loading under ASP.NET. Do not be confused by the presence of the word "Web" in the name – the

same assemblies are needed outside of Web applications as well.

The .NET assemblies are also necessary when you are using COM components for OPC. They are implemented in .NET, and exposed to the COM worlds using a COM interop.

When specifically selected during an installation (with the "Embedded assemblies" install component, or as part of the Full install), additional assemblies (that are normally embedded within OPC Data Client assemblies and thus invisible to the developer) are placed alongside the usual OPC Data Client assemblies. These assemblies are needed in certain rare situations, e.g. when registering type libraries for the dependent assemblies for COM interop, or under certain hosting environments or in some development tools.

Assemblies for .NET Framework are also used when you target the Excel as a development platform, with **Excel Option (Section 12.1)**.

Assemblies for .NET Standard

In .NET Standard, the OPC Data Client are not installed using a **Setup Program (Section 3.1.1)**. Instead, they are provided in form of **NuGet Packages (Section 3.1.2)**, available from www.nuget.org. The assemblies do not have a fixed or "well-known" installation location on your computer, and are installed separately into each project that uses them.

In addition, the OPC Data Client NuGet packages have dependencies on other NuGet packages, and so on. The precise structure and content of these dependencies depends on the targeted runtime. Consequently, by installing the OPC Data Client NuGet package(s) into your project, it ends up referencing more (possibly many) assemblies than explicitly listed here.

Strong-naming

As a general rule, OPC Data Client assemblies are strong-named.

An exception to this rule is made when we need to reference other assemblies that are not strong-named. In such case, we move such parts into a separate OPC Data Client assembly that is not strong-named. Usage of these parts is always optional and depends on the functionality you need. An example of this approach is the OpcLabs.Pcap assembly, which references the SharpPcap and PacketDotNet assemblies. You only need it when your application uses OPC UA PubSub Ethernet mapping, or when it works with Wireshark capture files.

The OPC Data Client assemblies that are strong-signed cannot directly reference the assemblies that are not strong-signed. For this reason, the assemblies that are strong-signed load the assemblies that are not strong-signed dynamically. Consequently, different (and platform-dependent) rules apply to where such assemblies are being searched for.

Also, assemblies that are not strong-signed cannot be put to GAC (Global Assembly Cache).

4.1.1.1 XML Comments

Together with the .DLL files of the assemblies, there are also .XML files that contain XML comments for them. The texts contained in these files are used by various tools to provide features such as IntelliSense and Object Browser information in Visual Studio.

4.1.1.2 ReSharper Annotations

API members are annotated using JetBrains ReSharper (http://www.jetbrains.com/resharper/) attributes, such as the most common **[CanBeNull]** and **[NotNull]** attributes. ReSharper users benefit from the annotations, as possible improper

usages are recognized and highlighted by ReSharper's code inspection feature.

4.1.2 COM Components

At the core of OPC Data Client-COM there are COM components that contain reusable library code. You reference these components from the code of your application, and by instantiating objects from those components and calling methods on them, you gain the OPC functionality.

In This Topic

COM components for OPC "Classic" and OPC UA are implemented in .NET, and exposed to the COM worlds using a COM interop. As such, they are contained in the .NET assemblies described under a corresponding chapter earlier, and installed in a subdirectory called **Assemblies\net47** under the installation directory of the product.

The assemblies become usable from a COM world by registering them using the Regasm.exe (Assembly Registration Tool), which is a part of .NET Framework. The OPC Data Client installation program registers the assemblies for COM interop automatically.

The Assembly Registration tool reads the metadata within an assembly and adds the necessary entries to the registry, which allows COM clients to create .NET Framework classes transparently. Once a class is registered, any COM client can use it as though the class were a COM class. The class is registered only once, when the assembly is installed. Instances of classes within the assembly cannot be created from COM until they are actually registered.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

4.1.2.1 Type Libraries (COM)

In Microsoft COM, the components are described by their corresponding Type Libraries. Type libraries are binary files (.tlb, .dll or .exe files) that include information about types and objects exposed by an ActiveX (COM) application. A type library can contain any of the following:

In This Topic

- Information about data types, such as aliases, enumerations, structures, or unions.
- Descriptions of one or more objects, such as a module, interface, IDispatch interface (dispinterface), or component object class (coclass). Each of these descriptions is commonly referred to as a typeinfo.
- References to type descriptions from other type libraries.

By including the type library with OPC Data Client, the information about the objects in the library is made available to the users of the applications and programming tools.

All type libraries (those that that are not embedded within other specific .dll or .exe files) in are located under the **SDK**\lib subdirectory in the product installation folder. Type libraries for 64-bit development are located under **SDK\lib\x64**. Note that the interface exposed by OPC Data Client (including the size of integer types) is the same, regardless whether it is for

32-bit or 64-bit development; there are just slight "formal" differences caused by the way the type libraries for 32-bit vs. 64-bit development are generated. Most development can simply use the 32-bit type libraries under the **SDK\lib** subdirectory.

Note that it is not strictly necessary to use type libraries for COM development. With late binding, it is possible to make use of the COM objects of OPC Data Client "as they are". Type libraries are used mainly with early binding.

Whether or not to use the type libraries depends in part on the tool or language you are using. Some allow only late binding (e.g. VBScript), some may allow only early binding, and yet some allow both (e.g. VB6). When your tool allows both options, usually the early binding is better (for performance and type checking reasons), but there are also situations where late binding is still appropriate or necessary. Some of these situations have to do with particular "quirks" present in the tools.

For example, in order to assign atomic values (such as numbers or strings) to a State property of OPC Data Client objects, you will need to use late binding in VB6. This is because the property as declared as VARIANT, but VB6 treats it as Object, and does not allow the non-object values be stored into it with early binding.

As described earlier, COM components of OPC Data Client are actually created from .NET components, using COM interop tools from .NET Framework. For this reason, there is one COM type library for each assembly that contains the OPC Data Client components.

This means that following type libraries are available to you:

Type Library File	Title	Description
OpcLabs.BaseLib.tlb	OPC Labs Base Library Core	Supporting code
OpcLabs.BaseLibForms.tlb	OPC Labs Base Library Forms	Contains fundamental and common classes for Windows Forms.
OpcLabs.EasyOpcClassic.tlb	OPC Labs EasyOPC "Classic" Library	Contains classes that facilitate easy work with OPC Classic.
OpcLabs.EasyOpcForms.tlb	OPC Labs EasyOPC Forms	Contains classes that provide OPC-related (both "Classic and Unified Architecture) user interface.
OpcLabs.EasyOpcUA.tlb	EasyOPC-UA Library	Contains classes that facilitate easy work with OPC Unified Architecture.

This documentation is for OPC Data Client version 2020.2. This is known as the *external version* of the product. The *internal version* number is 5.58, and that is also the version of the type libraries.

Each of these libraries is marked with an internal version number of the product, e.g. 5.58. Many COM tools (including e.g. the Visual Basic's References dialog, or OleView), however, display the version number of a type library in a hexadecimal notation, but without giving any indication of it. This may lead to confusion, because e.g. for OPC Data Client internal version 5.58, the version gets displayed as 5.3a (a hexadecimal representation of the internal version). Be careful to interpret the version numbers correctly.

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

4.1.3 Demo Applications

OPC Data Client ships with several applications that demonstrate its usage and capabilities. Depending on the development development platform you target, there are:

- **.NET Framework Demo Applications (Section 4.1.3.1)**
- **COM Demo Applications (Section 4.1.3.2)**
- **Excel Demo Applications (Section 12.1.4)**

There are currently no demo applications for .NET Standard. Their purpose is served by the **Examples (Section 4.1.4)**.

4.1.3.1 .NET Framework Demo Applications

The demo applications for .NET Framework are categorized by the OPC technology they use:

(Section 4.1.3.1.1)

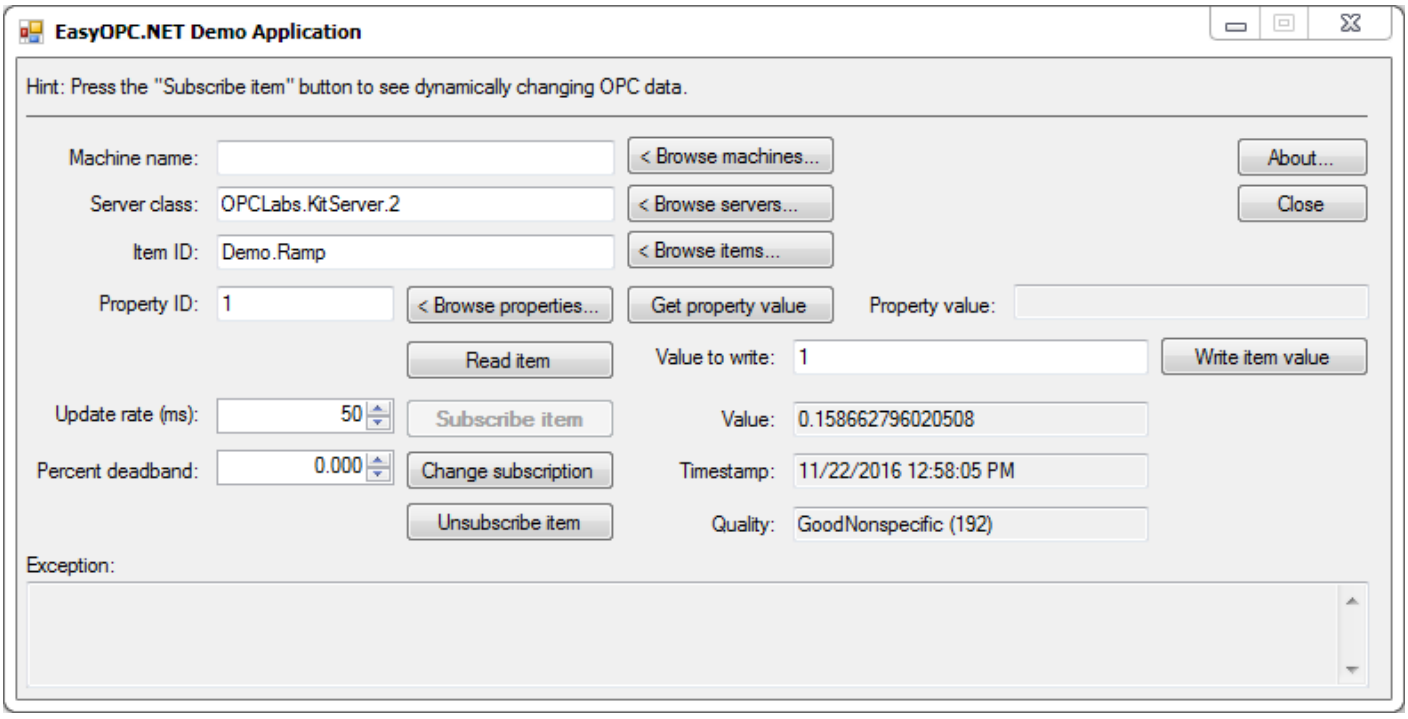
- **.NET Framework Demo Applications for OPC Classic (Section 4.1.3.1.1)**
- **.NET Framework Demo Applications for OPC UA (Section 4.1.3.1.2)**

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

4.1.3.1.1 .NET Framework Demo Applications for OPC Classic

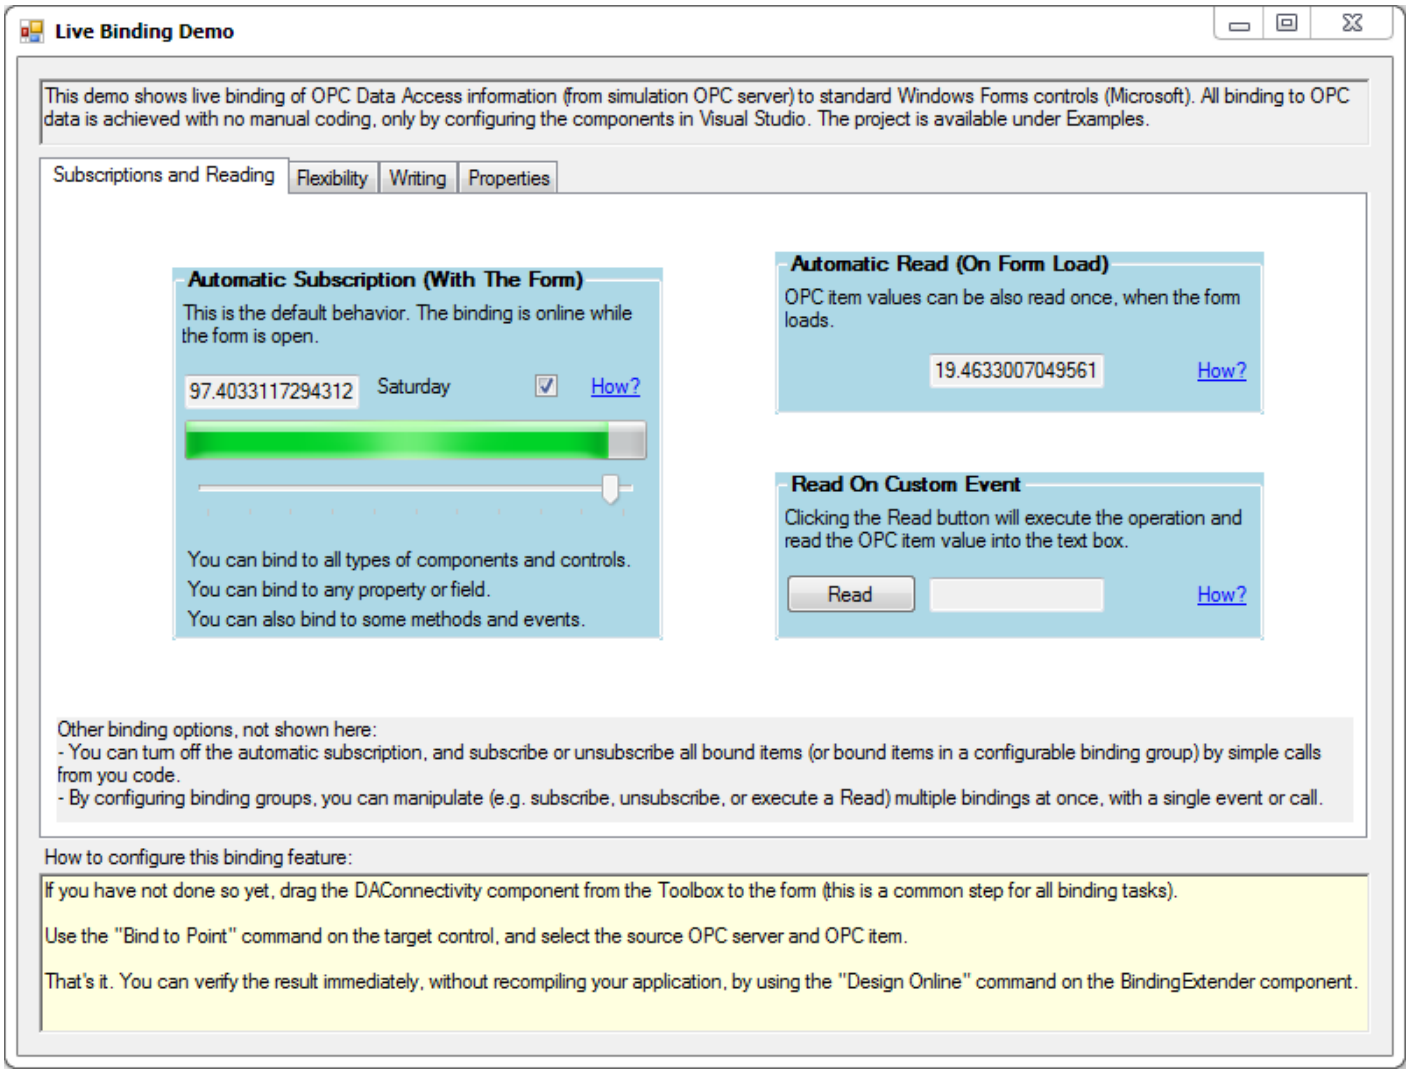
The OPC Data Client.NET demo applications are available from the Start menu or the Launcher application.

The basic demo is written using imperative programming model (explained further down in this document).



Note: There is also a similar application with an extra support for OPC XML-DA.

The Live Binding Demo shows live binding of OPC Data Access information (from simulation OPC server) to standard Windows Forms controls (Microsoft). All binding to OPC data is achieved with no manual coding, only by configuring the components in Visual Studio. This demo also serves as a tutorial application for the live binding development model: When you click on any of the “How?” links, the bottom pane displays instructions explaining how to configure that particular feature.



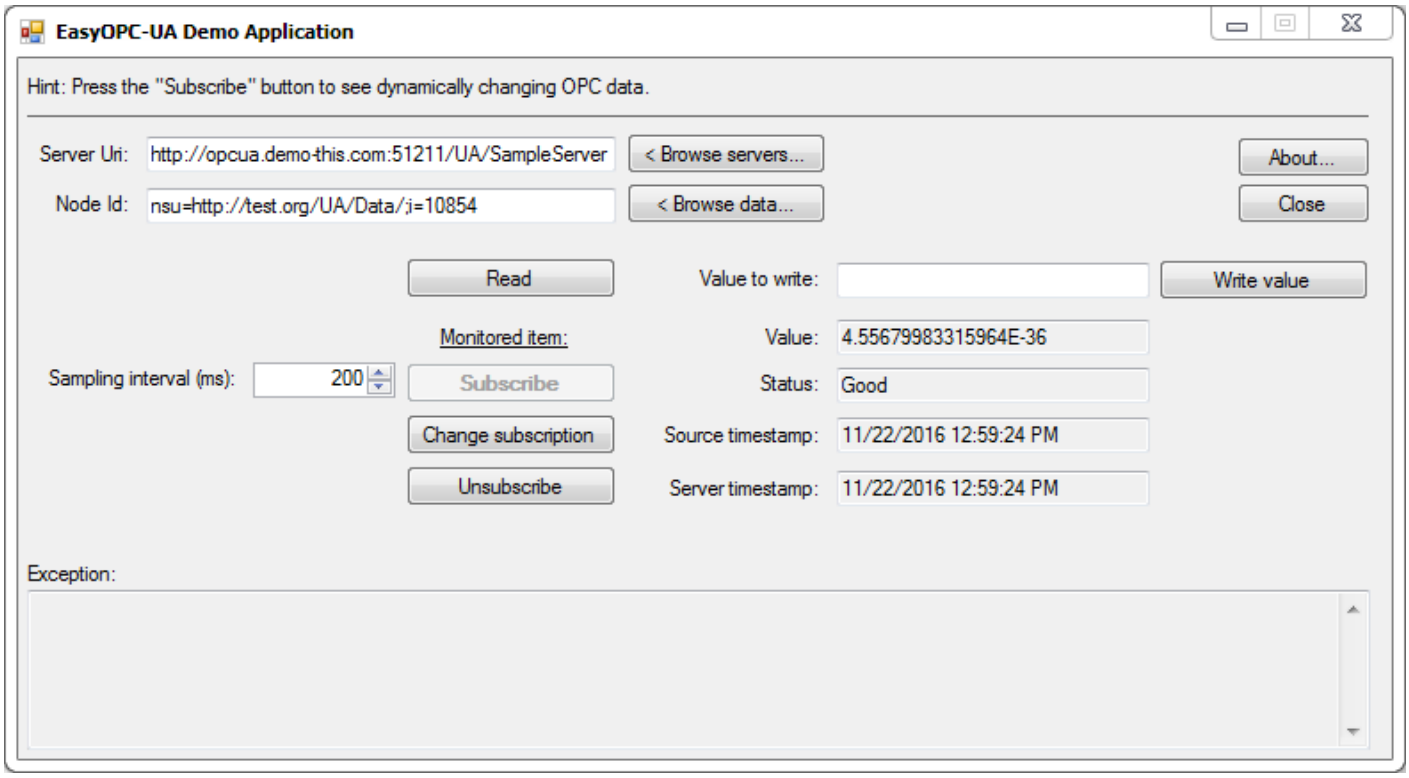
There are also several “integration demos”, showing how OPC Data Client features can be used in combination with other products that are not part of OPC Data Client. Following integration demos are currently available:

- Demo with Industrial Gadgets .NET
- Demo with Instrumentation Controls
- Demo with Symbol Factory .NET

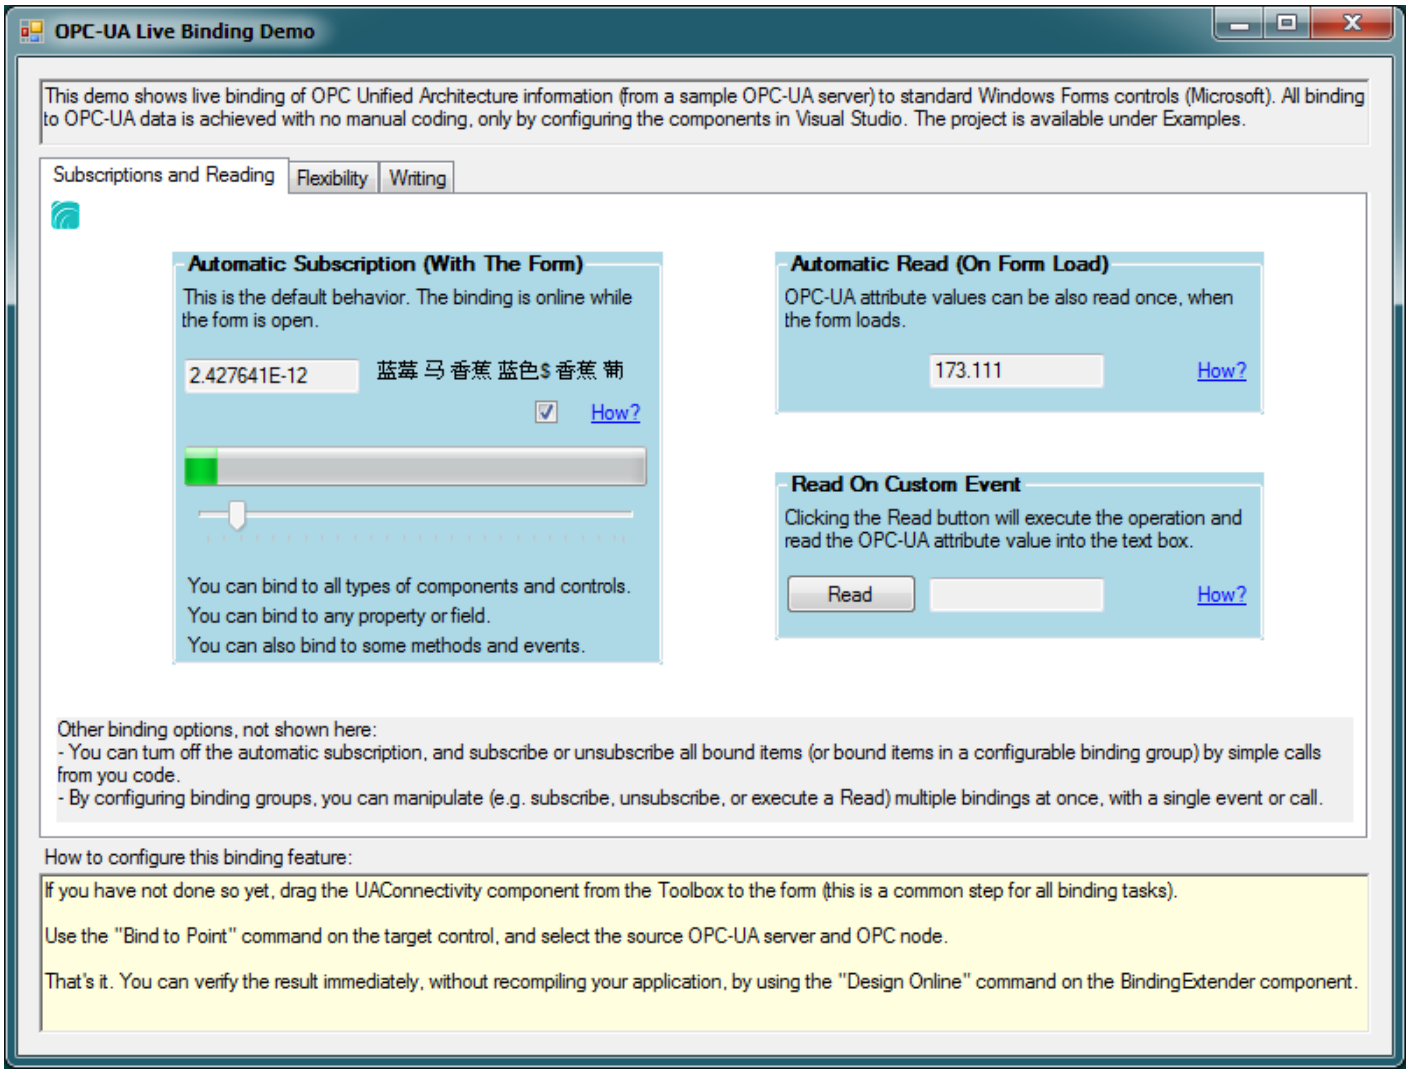
There is also a similar application that demonstrates the Live Binding capabilities with OPC Unified Architecture.

4.1.3.1.2 .NET Framework Demo Applications for OPC UA

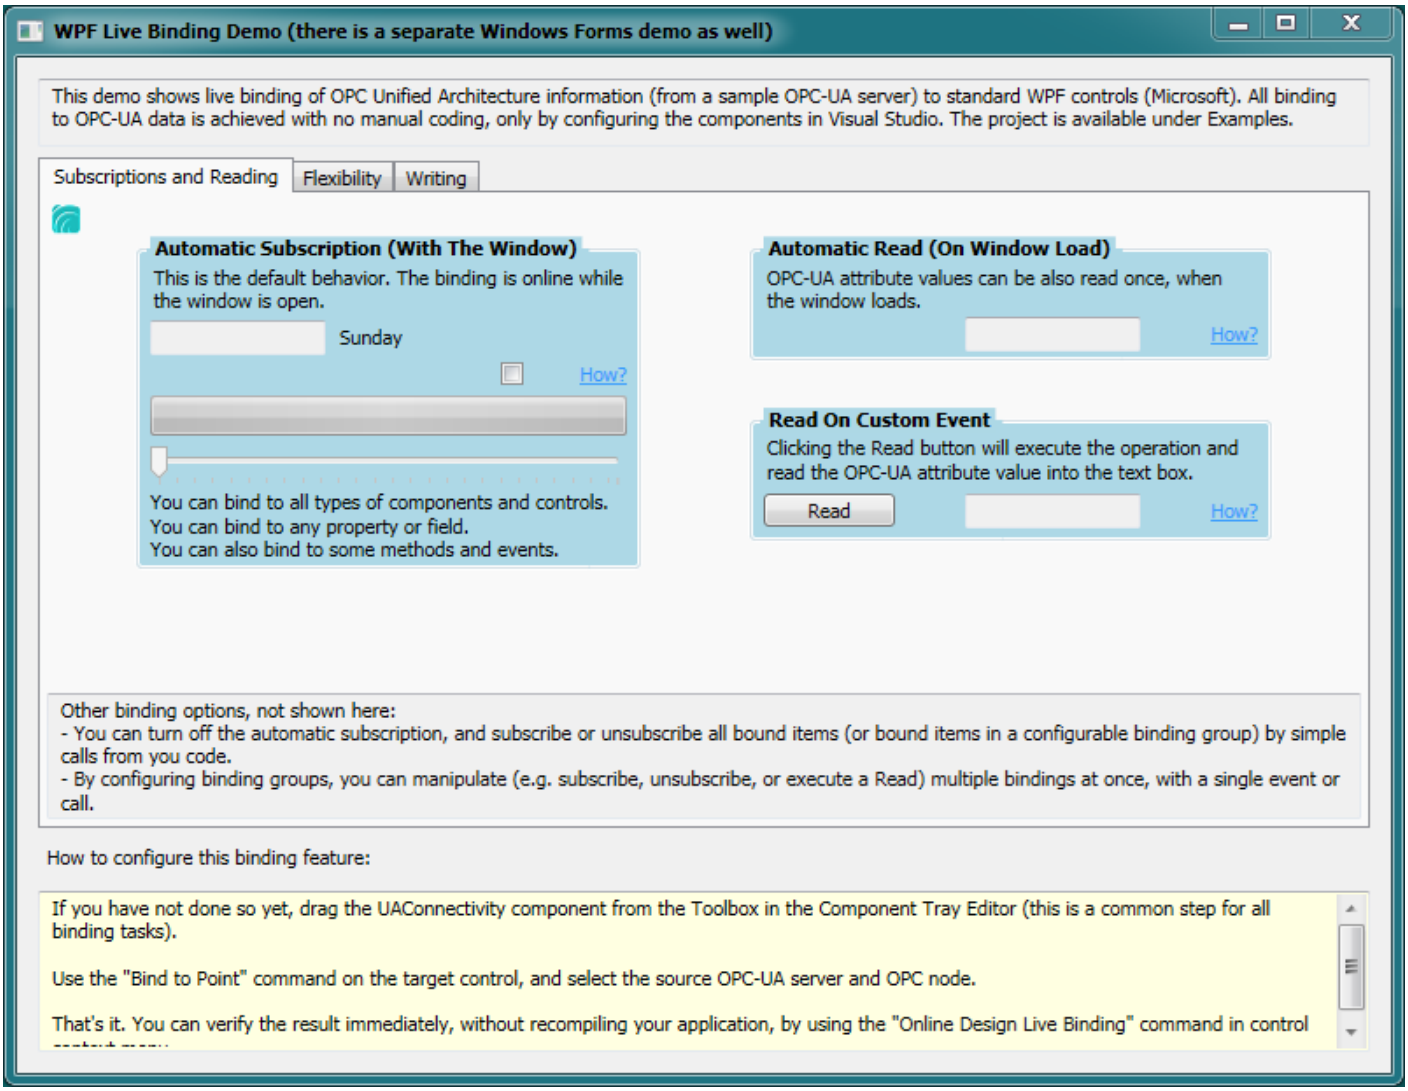
OPC Data Client-UA installs with a demo application that allows exploring various functions of the product. The demo application is available from the Start menu or the Launcher application.



The Live Binding Demo shows live binding of OPC Unified Architecture information (from simulation OPC server) to standard Windows Forms controls (Microsoft). All binding to OPC data is achieved with no manual coding, only by configuring the components in Visual Studio. This demo also serves as a tutorial application for the live binding development model: When you click on any of the “How?” links, the bottom pane displays instructions explaining how to configure that particular feature.

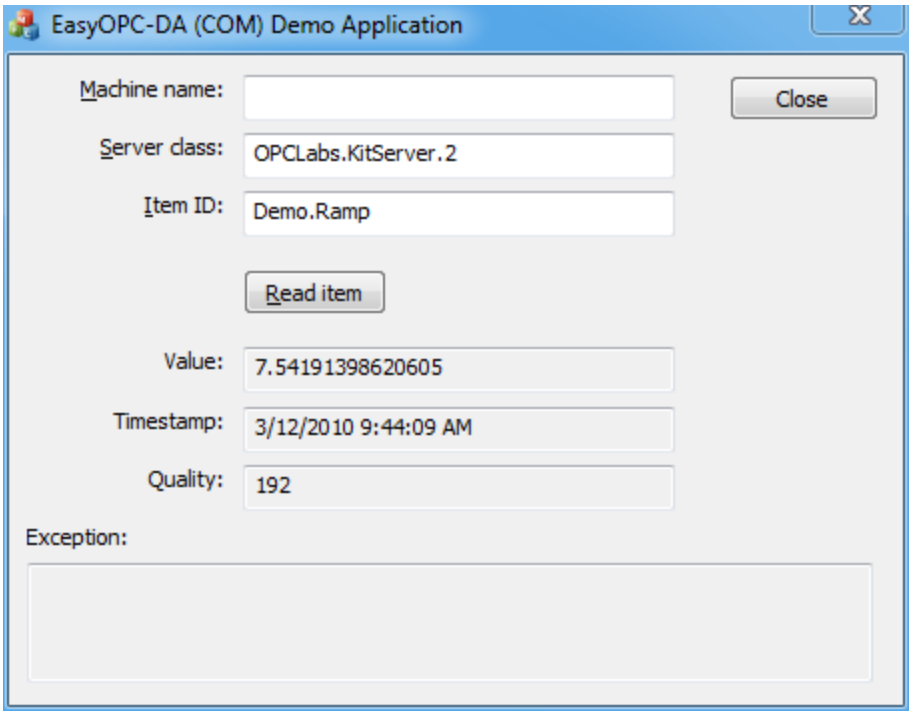


There is also a Live Binding demo application written for Windows Presentation Foundation (WPF), with functionality closely matching that of Windows Forms application:



4.1.3.2 COM Demo Applications

OPC Data Client-COM installs with a demo application that allows exploring basic functions of the product. The demo application is available from the Start menu or the Launcher application.



4.1.4 Examples

Example code, projects and solutions are available from the Start menu or the Launcher application (if you have used the **Setup Program (Section 3.1.1)** on Windows to install OPC Data Client). You can also access them from the file system:

- **COM Examples (Section 13.1.1)** (OPC Data Client-COM and OPC Data Client-UA for COM) are in the **Examples-COM** subfolder of the installation folder.
- **.NET Framework Examples (Section 13.1.2)** (OPC Data Client.NET and OPC Data Client-UA for .NET) are in the **Examples-NET** subfolder of the installation folder.
- **.NET Standard Examples (Section 13.1.3)** for .NET Core runtime are in the **Examples-NETCore** subfolder of the installation folder.

If you are developing for .NET Standard and have not used the **Setup Program (Section 3.1.1)**, you can download the **.NET Standard Examples (Section 13.1.3)** from the Web, in form of archives.

There is a separate **Examples (Section 13)** section in this document that contains list of all examples and their purpose, with chapters for **.NET Framework Examples (Section 13.1.2)**, **COM Examples (Section 13.1.1)** and **.NET Standard Examples (Section 13.1.3)**. You can access these documentation chapters from the Start menu as well.

4.1.4.1 LINQPad support

LINQPad (http://www.linqpad.net/) is a software utility for .NET that allows you to quickly and interactively test out C#, VB.NET and F# code without the need for an IDE. We highly recommend that you use this tool (free edition exists) for experiments and learning.

OPC Data Client works well with LINQPad. We have made some special tweaks for it as well, e.g. to ensure a proper expandable display of all types in LINQPad.

OPC Data Client standalone installer ships with examples for LINQPad; see the Examples section in this document for details. The NuGet packages include the LINQPad examples as well.

4.1.5 Documentation and Help

The documentation consists of following parts:

- **User's Guide and Reference (online)**. The reference is formatted according to Visual Studio style and standards, and integrates with Visual Studio help system. This document include, among other content:
  - Getting Started. Short step-by-step instructions to create your first project.
  - Examples in .NET Framework, .NET Standard and COM.
  - Documentation for StreamInsight Option and Excel Option.
  - Reference.
- **User's Guide (PDF, online)**. The content is same as User's Guide and Reference above, but the Reference part is not included.
- **What's New** (online). Contains information about changes made in this and earlier versions.

Because the COM components are implemented by exposing the .NET objects of OPC Data Client to COM, you may need to refer to OPC Data Client reference documentation in order to find information about COM objects and interfaces of OPC Data Client as well.

You can access all the above mentioned documentation from the **Start** menu or the **Launcher** application.

In addition, there is IntelliSense and Object Browser information available from the Visual Studio environment.

The OPC Data Client help contents integrate Microsoft Visual Studio 2017/2019 Help (Microsoft Help Viewer 2 format). This also means that the reference documentation works as a contextual help; e.g. pressing F1 when the cursor is on some of the OPC Data Client types or members invokes directly the help page for that type or member.

> ⚠ See TechNet article Visual Studio 2017: Getting Started with Help Viewer for information about how to enable offline documentation in Visual Studio.
>
> In addition, for the contextual help to work, you need to have the help preference set properly. In Visual Studio, do this:
>
> Help -> Set Help Preference -> Launch in Help Viewer
>
> (i.e. **not** Launch in Browser).

4.1.6 Bonus Material

Bonus Material

From OPC Labs Knowledge Base
Jump to navigation Jump to search

Introduction

The QuickOPC installation also contains bonus tools and materials related to the product. The bonus material may be updated and enhanced more frequently than the base product, but it is not an official part of the product, and support for it is not guaranteed.

Note that some tools are only available with or related to QuickOPC-COM, QuickOPC.NET or QuickOPC-UA. In such case, they are labeled accordingly, or marked with corresponding COM or .NET icon further down in the text.

OPC-DA Quality Decoder

Enter the (rather cryptic) OPC-DA quality value that some tools display, press “Decode”, and this application will decode the value and show you the various bit fields contained in the OPC-DA quality.

This is a WPF (Windows Presentation Foundation) application. Its source code is included in the examples solution.

UA Configuration Tool

This is an OPC Foundation tool, providing a centralized place to configure the applications based on the .NET stack, manage application certificates, manage certificate repositories, and COM interoperability. For documentation, see

- Launching the UA Configuration Tool, and
- UA Configuration Tool Overview.

The UA Configuration Tool is under OPC Foundation MIT License 1.00, whose text is also included (in **license.txt** file) in the installatrion folder of the tool.

4.1.7 Tools and Online Services

Besides offering components to integrate within your project, OPC Data Client also offers several tools and online service that can assist you in development. They include:

- **License Manager (Section 11.1)** - GUI, and **LMConsole Utility (License Manager Console) (Section 11.1.1)**
- **Connectivity Explorer (Section 11.2)**
- **The Launcher application (Section 11.3)**
- **OpcCmd Utility (Section 11.4)**
- **Demo Servers and Publishers (Section 11.5)** (some installable locally, some are online)

4.2 Typical Usage

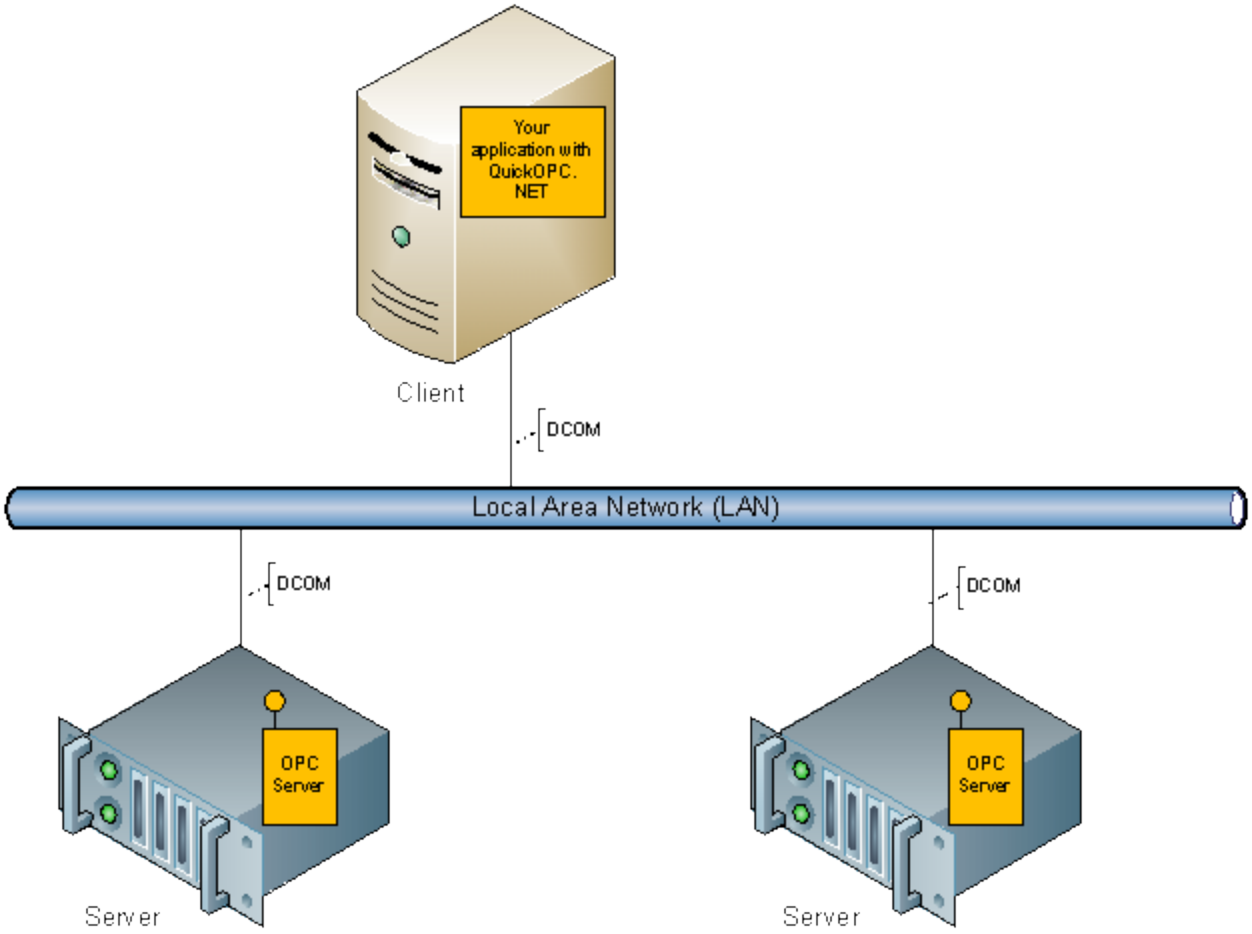
OPC Data Client.NET and OPC Data Client-UA for .NET are suitable for use from within any tool or language based on Microsoft .NET. There are many different scenarios for it, but some are more common.

OPC Data Client-COM and OPC Data Client-UA for COM are suitable for use from within any tool or language based on Microsoft (COM) Automation. There are many different scenarios for it, but some are more common.

4.2.1 OPC Classic thick-client .NET applications on LAN

The most typical use of OPC Data Client.NET involves a thick-client user application written in one of the Microsoft .NET languages. This application uses the types from OPC Data Client.NET object model, and accesses data within OPC servers that are located on remote computers on the same LAN (Local Area Network). The communication with the target OPC server is performed by Microsoft COM/DCOM technology.

The following picture shows how the individual pieces work together:

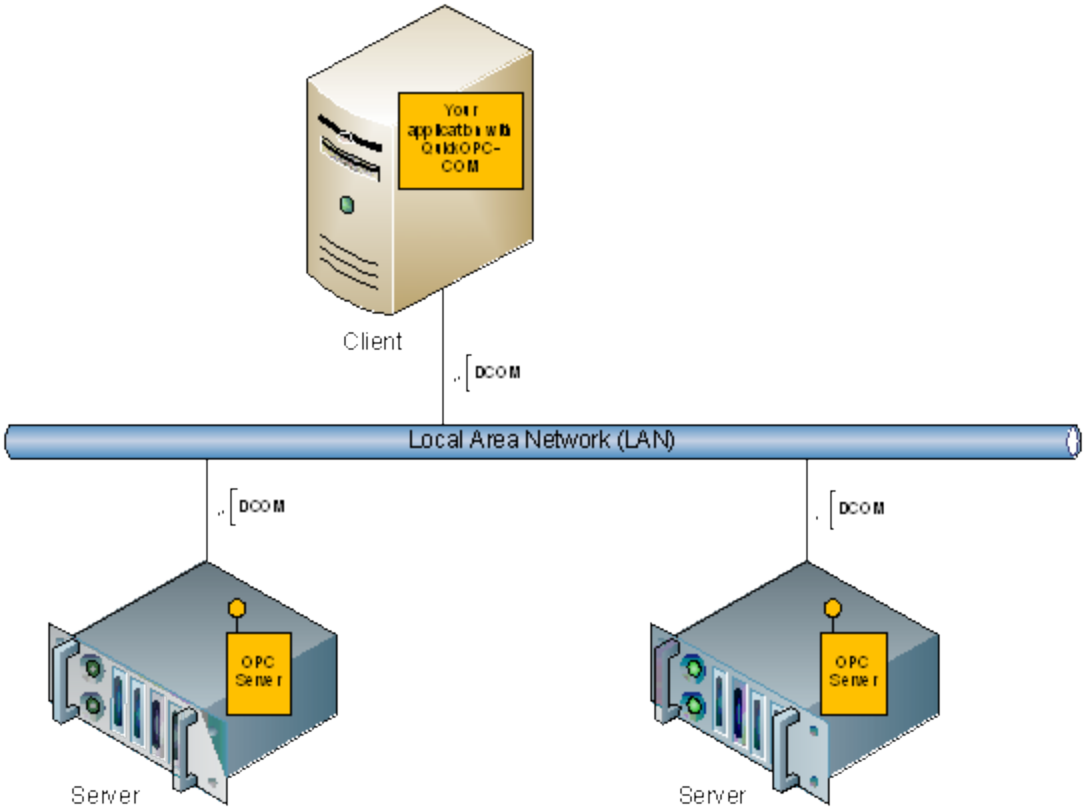


4.2.2 OPC Classic or OPC UA thick-client COM applications on LAN

The most typical use of OPC Data Client-COM or OPC Data Client-UA for COM involves a thick-client user application written in a tool or language that supports COM automation. This application uses the types from OPC Data Client-COM (or OPC Data Client-UA for COM) object model, and accesses data within OPC servers that are located on remote computers on the same LAN (Local Area Network). The communication with the target

OPC server is performed by Microsoft COM/DCOM technology.

The following picture shows how the individual pieces work together:



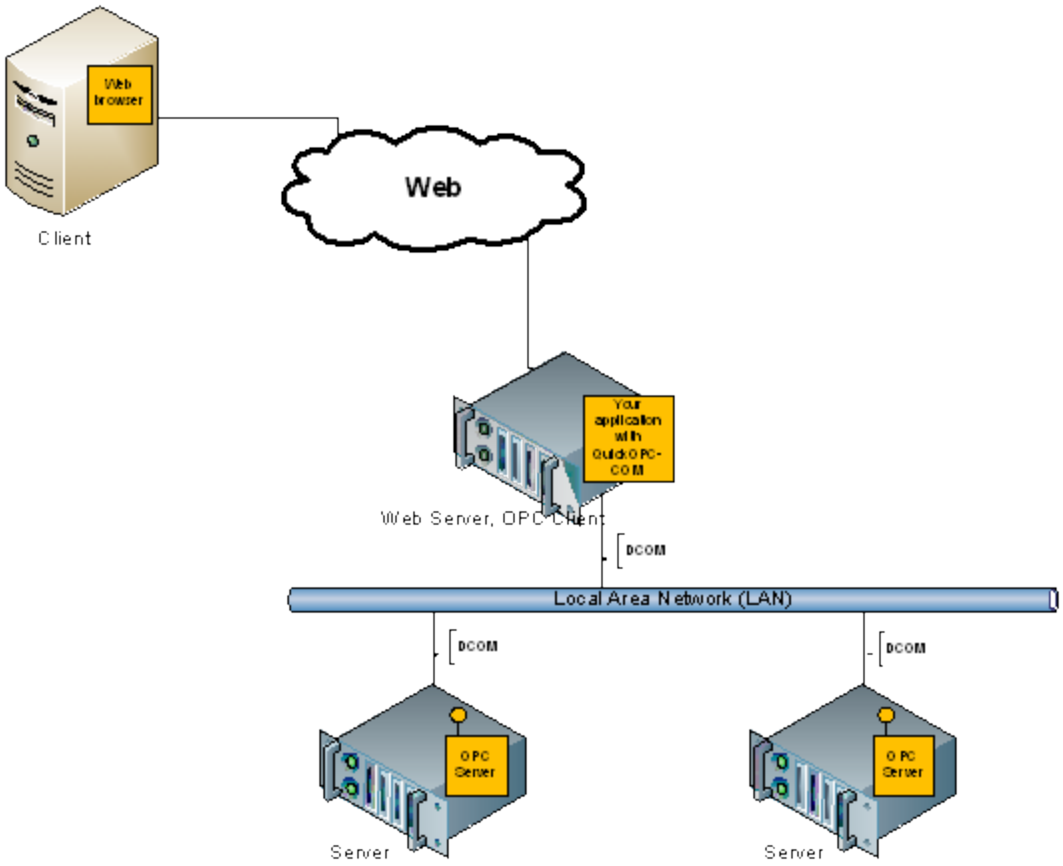
4.2.3 OPC Classic Web applications (server side)

The other typical use of OPC Data Client is to place it on the Web server inside a Web application. The Web application provides HTML pages to the client's browser, runs in a Web server, such as Microsoft IIS (Internet Information Server), and is written using tools and languages such as

- ASP/VBScript, PHP, Python and others – any language that supports COM automation, or
- ASP.NET, C#, Visual Basic.NET, or any other .NET language.

The Web application uses the types from OPC Data Client object model, and accesses data within OPC servers that are located on remote computers on the same LAN (Local Area Network). The communication with the target OPC server is performed by Microsoft COM/DCOM technology. No OPC-related (or indeed, COM or Microsoft-related) software needs be installed on the client machine; a plain Web browser such as Internet Explorer (IE) or FireFox is sufficient.

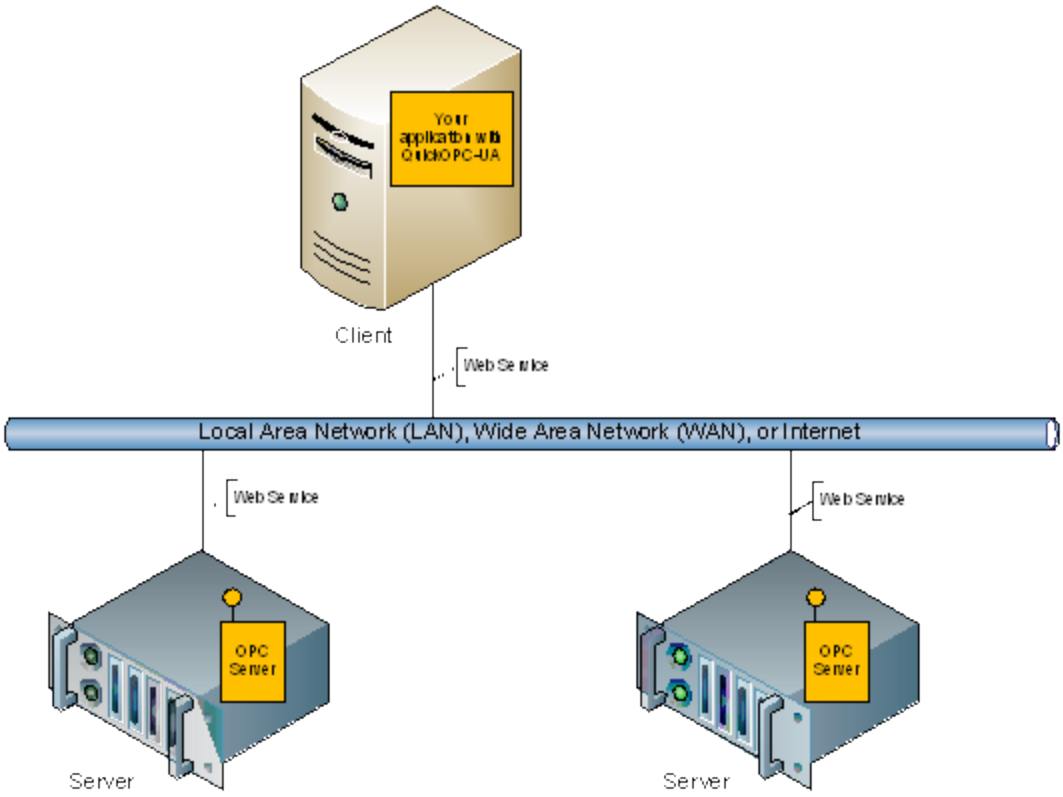
The following picture shows how the individual pieces work together:



4.2.4 OPC UA Thick-client applications on LAN, WAN or Internet

The most typical use of OPC Data Client-UA involves a thick-client user application written in one of the Microsoft .NET languages. This application uses the types from OPC Data Client-UA object model, and accesses data within OPC servers that are located on remote computers on the same LAN (Local Area Network) or on WAN (Wide Area Network) or on the Internet. The communication with the target OPC server is performed by means of Web Services.

The following picture shows how the individual pieces work together:

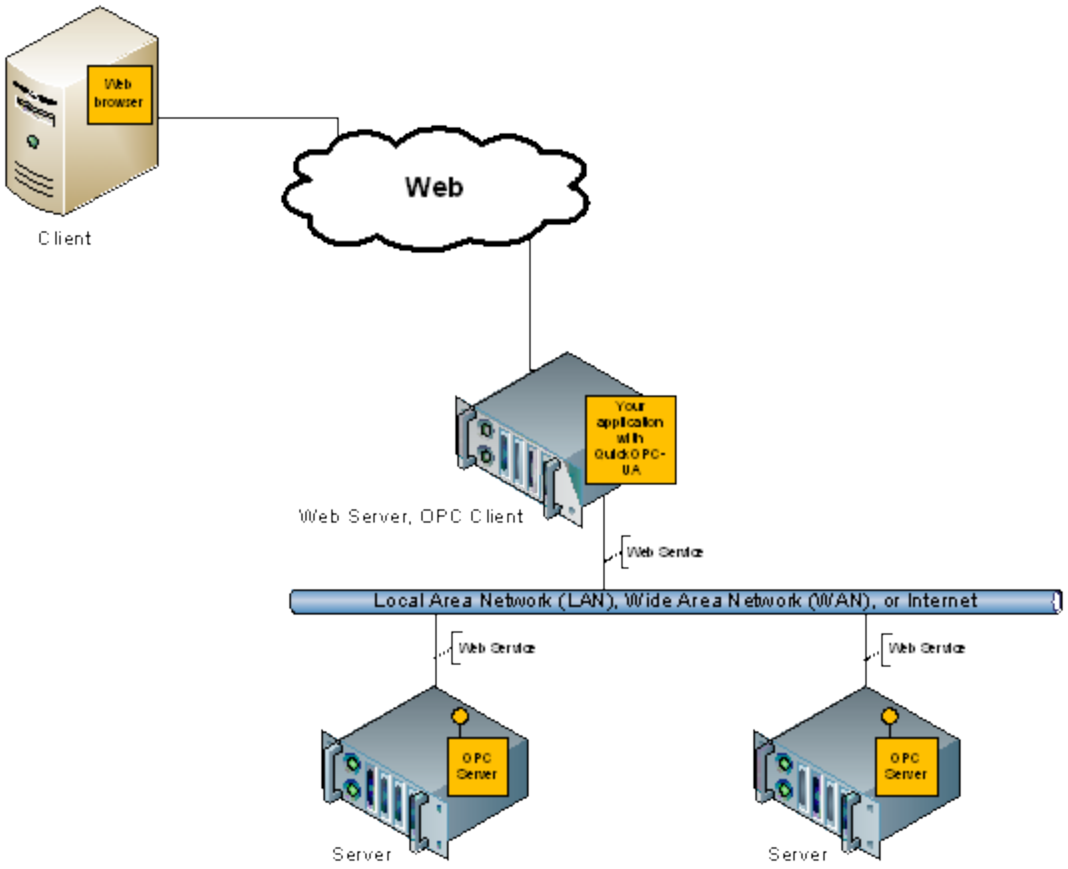


4.2.5 OPC UA Web applications (server side)

The other typical use of OPC Data Client-UA is to place it on the Web server inside a Web application. The Web application provides HTML pages to the client's browser, runs in a Web server, such as Microsoft IIS (Internet Information Server), and is written using tools and languages such as ASP.NET (using C#, Visual Basic.NET, or other .NET language).

The Web application uses the types from OPC Data Client-UA object model, and accesses data within OPC servers that are located on remote computers on the same LAN (Local Area Network). The communication with the target OPC server is performed by means of Web Services. No OPC-related (or indeed, Microsoft-related) software needs be installed on the client machine; a plain Web browser such as Internet Explorer (IE) or Firefox is sufficient.

The following picture shows how the individual pieces work together:



4.3 Referencing the Assemblies (.NET)

In .NET, in order to take advantage of the functionality provided by OPC Data Client, you need to reference its assemblies in your own project.

The following chapters describe how this is done. They provide **Overview of the Assemblies Available (Section 4.3.1)**, and discuss the various ways to reference assemblies:

- **Manual Assembly Referencing (Section 4.3.2)**
- **Assembly Referencing with Visual Studio Toolbox (Section 4.3.3)**
- **Assembly Referencing with NuGet (Section 4.3.4)**

In addition, **Licensing in Visual Studio (Section 4.3.5)** and the **.NET Namespaces (Section 4.3.6)** provided by OPC Data Client are described.

4.3.1 Overview of the Assemblies Available

Most projects will need:

- "**OPC Labs Base Library Core**" (OpcLabs.BaseLib.dll)
- for OPC Classic: "**OPC Labs EasyOPC "Classic" Library**" (OpcLabs.EasyOpcClassic.dll)
- for OPC UA: "**EasyOPC-UA Library**" (OpcLabs.EasyOpcUA.dll)

Some project will also need other assemblies, such as

- "**OPC Labs Base Library Forms**" (OpcLabs.BaseLibForms.dll) **(not in .NET Standard)**
- "**OPC Labs Base Library Presentation**" (OpcLabs.BaseLibPresentation.dll) **(not in .NET Standard)**
- "**OPC Labs EasyOPC Forms**" (OpcLabs.EasyOpcForms.dll) **(not in .NET Standard)**

You do not need to (and should not) ever reference the following assemblies:

- **EasyOPC "Classic" Raw Library (x64)** (App_Web_OpcLabs.EasyOpcClassicRaw.amd64.dll)
- **EasyOPC "Classic" Raw Library (x86)** (App_Web_OpcLabs.EasyOpcClassicRaw.x86.dll)

This does not mean that these assemblies are useless or are not used. They are used indirectly, by the relevant assemblies that you do reference, and they will copied over to the target automatically by the build tools.

In OPC UA PubSub, if you want to work with raw Ethernet packet mappings, or Wireshark capture files, the OpcLabc.Pcap assembly must be made available to your program - usually you achieve it by referencing this assembly, although it is not directly used by your code.

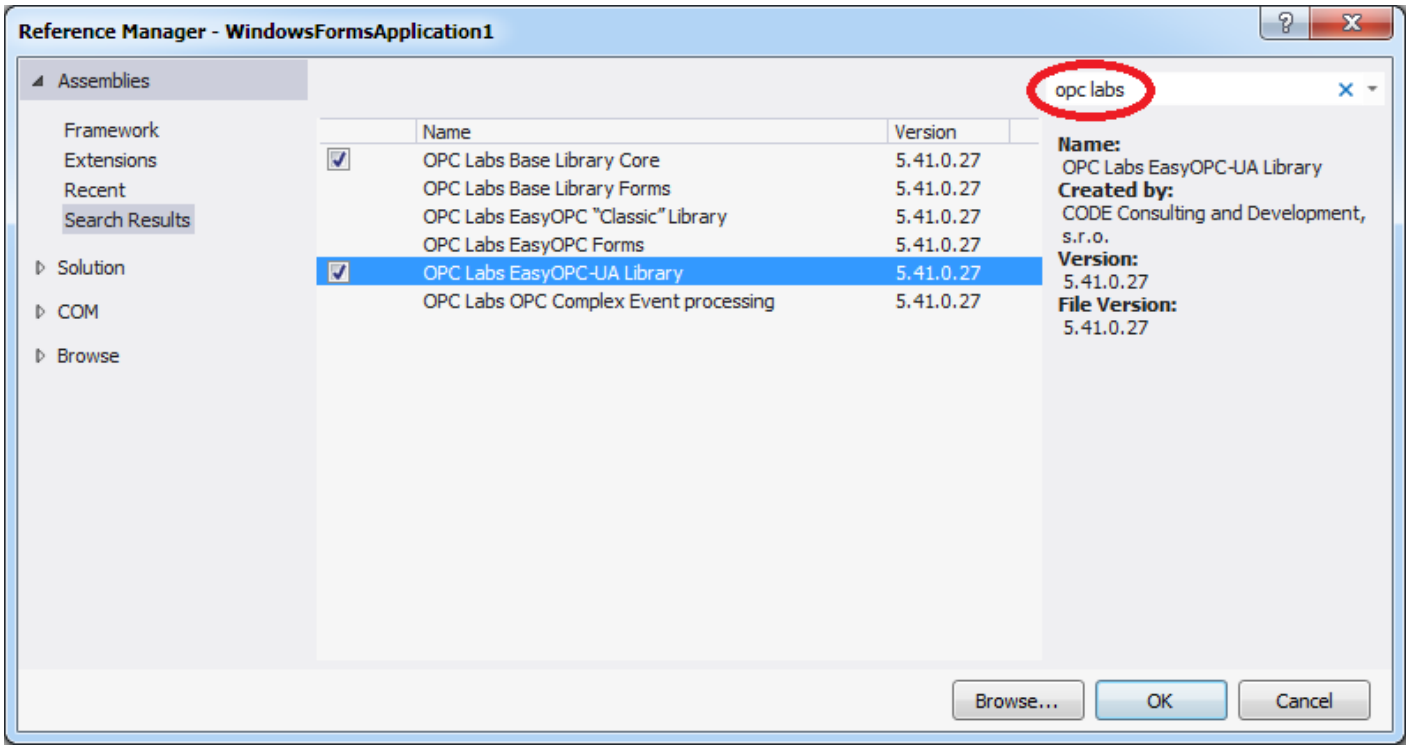
4.3.2 Manual Assembly Referencing

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

Your application first needs to reference the OPC Data Client.NET or OPC Data Client-UA assemblies in order to use the functionality contained in them. How this is done depends on the language and tool you are using:

- For Visual Basic in Visual Studio, select the project in Solution Explorer, and choose Project -> Add Reference command.
- For Visual C# in Visual Studio, select the project in Solution Explorer, and choose Project -> Add Reference command.
- For Visual C++ in Visual Studio, select the project in Solution Explorer, and choose Project -> References command.

You are then typically presented with an "Add Reference" dialog. The OPC Data Client "Classic" and OPC Data Client-UA assemblies are listed under its Assemblies (or .NET) tab. Select those that you need (see their descriptions in "Product Parts" chapter), and press OK.



You can easily see all OPC Data Client assemblies grouped together (as in the picture above), if you type "opc labs" into the search box. You can also sort the list alphabetically by Component Name, by clicking on the corresponding column header; then, scroll to the proper place in the list.

Notes:

- The list content is pulled in background, so you may need to wait a little until all components are listed and you can properly sort them or search for them.
- This documentation is for **OPC Data Client version 2020.2**. This is known as the *external version* of the product. The *internal version* number is **5.58**, and that is how the assemblies are listed in the Reference Manager.
- OPC Data Client.NET assemblies need the .NET Framework 4.7 or later. The dialog filters the components according to the target platform setting of you project. You will not see OPC Data Client.NET assemblies listed them listed if your project's target framework is not set to .NET Framework 4.7 or later.

4.3.3 Assembly Referencing with Visual Studio Toolbox

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

If you are using the Visual Studio Toolbox (described further below) to add instances of components to your project, the assembly references are created for you by Visual Studio automatically, when you drag the component onto the designer's surface.

This is the approach used in the "Getting Started" articles:

- **Making a first OPC Classic application using Live Binding in Windows Forms (Section 3.2.1.1)**
- **Making a first OPC Classic application using traditional coding (Section 3.2.1.2)**
- **Making a first OPC UA application using Live Binding in Windows Forms (Section 3.2.2.1)**
- **Making a first OPC UA application using Live Binding in WPF (Section 3.2.2.2)**
- **Making a first OPC UA application using traditional coding (Section 3.2.2.3)**

This technique only works for certain kinds of projects (such as Windows Forms or WPF) and certain kinds of project items in them.

4.3.4 Assembly Referencing with NuGet

If you have used NuGet to install a OPC Data Client package into your project, all necessary assembly references are done for you automatically. See **NuGet Packages (Section 3.1.2)** in the **Installation (Section 3.1)** chapter for details on how to install the NuGet packages into your project.

This is the main technique used for referencing assemblies in projects targeting .NET Standard development platform.

You may, however, sometimes want to *remove* certain assembly references later, if you do not need them. For example, the **OpcLabs.QuickOpc** package will automatically reference the assemblies needed for all supported OPC technologies, but if you do not need e.g. OPC "Classic" or OPC Unified Architecture at all, you may remove the corresponding assembly references from your project.

4.3.5 Licensing in Visual Studio

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

OPC Data Client uses, in part, .NET licensing model for component and controls. The internal working of it are largely invisible to you. The visible manifestation of the licensing model in Visual Studio is that the designer creates and maintains a file named **licenses.licx**, which contains a list of the licensed components, together with their assembly and version information. The file is also automatically updates when you upgrade to a newer version of build of OPC Data Client. You can safely rely on Visual Studio maintaining this file.

As opposed to other components and controls that use this licensing model in full, OPC Data Client license keys do not actually get embedded into your compiled project. The OPC Data Client license should always be installed onto the machine separately, using e.h. the License Manager utility of OPC Data Client.

4.3.6 .NET Namespaces

The OPC Data Client "Classic" and OPC Data Client-UA class libraries are made up of namespaces. Each namespace contains types that you can use in your program: classes, structures, enumerations, delegates, and interfaces.

All our namespaces begin with OpcLabs name. OPC Data Client "Classic" and OPC Data Client-UA define types mainly in namespaces described in tables under the links below.

- In OpcLabs.BaseLib Assembly
- In OpcLabs.BaseLibForms Assembly
- In OpcLabs.BaseLibPresentation Assembly
- In OpcLabs.EasyOpcClassic Assembly
- In OpcLabs.EasyOpcUA Assembly

You can use symbols contained in the namespaces by using their fully qualified name, such as OpcLabs.EasyOpc.DataAccess.EasyDAClient. In order to save typing and achieve more readable code, you will typically instruct your compiler to make the namespaces you use often available without explicit reference. To do so:

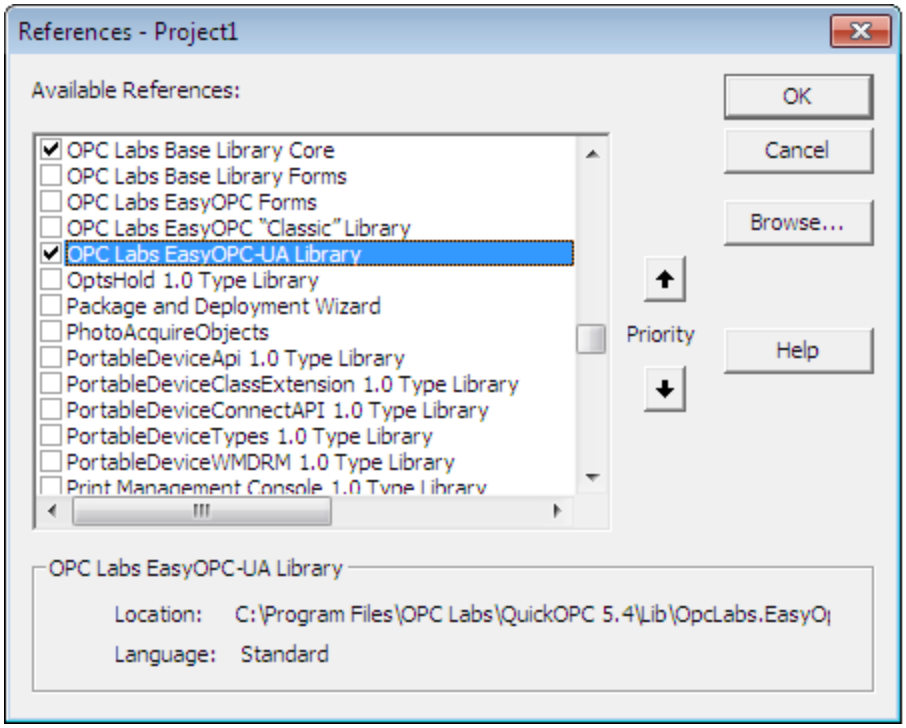
- In Visual Basic (VB.NET), place the corresponding Imports statements at the beginning of your code files.
- In Visual C#, place the corresponding using directives at the beginning of your code files.
- In Visual C++, place the corresponding using namespace directives at the beginning of your code files.
- In Visual F#, place the corresponding open directives at the beginning of your code files.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

4.4 Referencing the Components (COM)

Your application first needs to reference the OPC Data Client-COM or OPC Data Client-UA for COM components in order to use the functionality contained in them. How this is done depends on the language and tool you are using.

In Visual Basic 6.0 and Visual Basic for Applications (e.g. Microsoft Excel, Word, Access, PowerPoint, and many non-Microsoft tools), select Project -> References (or Tools -> References) from the menu. You are then presented with a **References** dialog. The OPC Data Client-COM type libraries should be listed in alphabetical order, prefixed with **"OPC Labs"** in their name so that you can easily find them grouped together:



Check the boxes next to the libraries you are referencing, and press OK.

Some tools provide a different user interface for referencing the components, while yet others do not have any user interface at all, and you need to write a source code statement that references the type library directly.

If the library you are looking for is not listed, it may be necessary to specify its location explicitly. Sometimes, simply restarting the Visual Basic 6.0 helps. Otherwise, press the Browse... button (or a corresponding UI element in other tools), and navigate to the **SDK\lib** subdirectory of the OPC Data Client product installation folder on your disk. Then, select the

type library file you are looking for (e.g. **OpcLabs.BaseLib.tlb** for "OPC Labs Base Library Core").

Note that referencing the type library in WSH (Windows Script Host) or ASP is only needed if you want to use certain features, such as the named constants included in the library. It is not necessary to reference the type library for simply instantiating the components and making methods calls, as for method calls, VBScript or JScript code in WSH or ASP can interrogate the created objects and use late binding to perform the calls.

It is also possible to do away with referencing the component in Visual Basic 6.0 and Visual Basic for Applications, and proceed simply to instantiating the object(s) as described further below, in a way similar to VBScript, but you would lose several features such as the early-binding, IntelliSense, and ability to use symbolic objects names and enumeration constants from the type library.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

4.4.1 COM Components for OPC Classic

In order to gain access to all COM objects of OPC Data Client "Classic", you need types described in the following type libraries:

Type Library Name	LIBID	Note
OPC Labs Base Library Core	ecf2e77d-3a90-4fb8-b0e2-f529f0cae9c9	
OPC Labs Base Library Forms	A0D7CA1E-7D8C-4D31-8ECB-84929E77E331	only for User Interface objects
OPC Labs EasyOPC "Classic" Library	1F165598-2F77-41C8-A9F9-EAF00C943F9F	
OPC Labs EasyOPC Forms	2C654FA0-6CD6-496D-A64E-CE2D2925F388	only for User Interface objects

For illustration and for your convenience, we have listed below examples of source code reference statements for the "OPC Labs EasyOPC "Classic" Library" in various languages and tools.

Language/tool	Statement
C++	#import"libid:1F165598-2F77-41C8-A9F9-EAF00C943F9F" // OpcLabs.EasyOpcClassic
WSH	<referenceguid="{1F165598-2F77-41C8-A9F9-EAF00C943F9F}" /> <!--OpcLabs.EasyOpcClassic-->
ASP	<!—METADATA TYPE="TypeLib" NAME="OPC Labs Easy "Classic" Library" UUID="{1F165598-2F77-41C8-A9F9-EAF00C943F9F}" -->

4.4.2 COM Components for OPC UA

In order to gain access to all COM objects of OPC Data Client-UA, you need types described in the following type libraries:

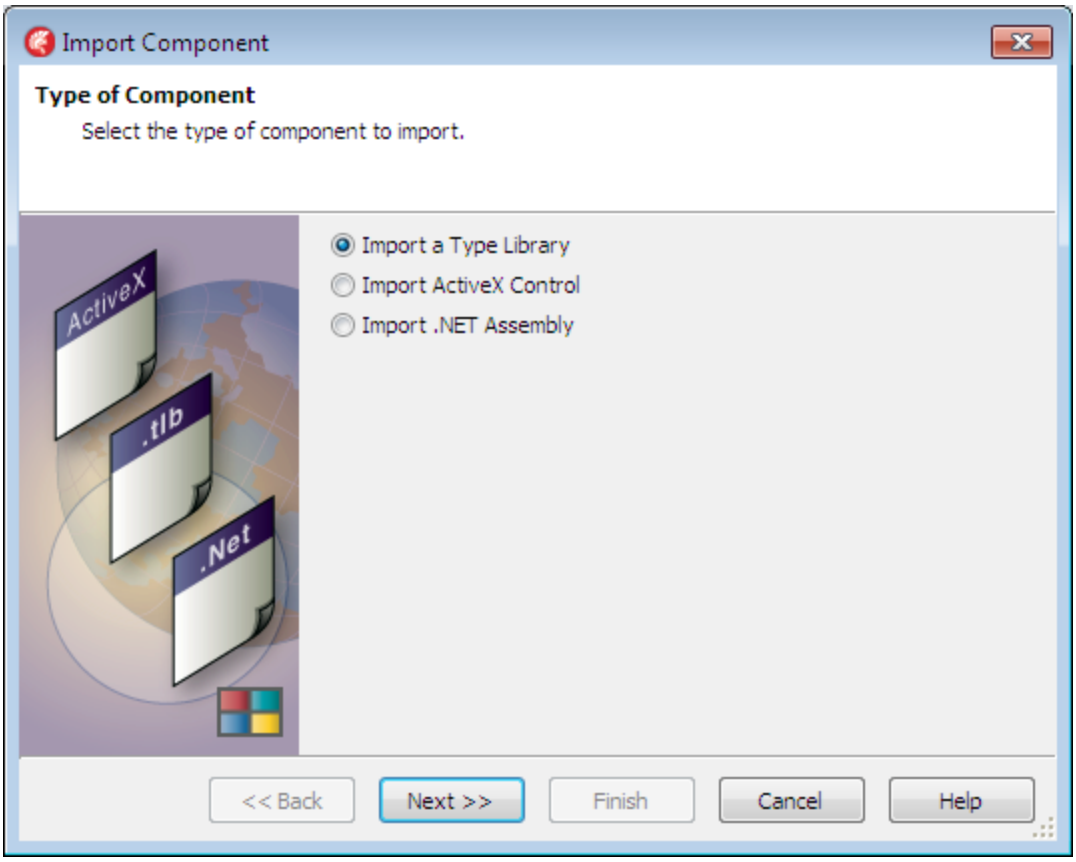
Type Library Name	LIBID	Note
OPC Labs Base Library Core	ecf2e77d-3a90-4fb8-b0e2-f529f0cae9c9	
OPC Labs Base Library Forms	A0D7CA1E-7D8C-4D31-8ECB-84929E77E331	only for User Interface objects
OPC Labs EasyOPC-UA Library	E15CAAE0-617E-49C6-BB42-B521F9DF3983	
OPC Labs EasyOPC Forms	2C654FA0-6CD6-496D-A64E-CE2D2925F388	only for User Interface objects

4.4.3 Importing Type Libraries to Delphi

Use the steps below to import OPC Data Client-UA for COM type libraries to Delphi XE7, Delphi XE8 or Delphi 10 Seattle.

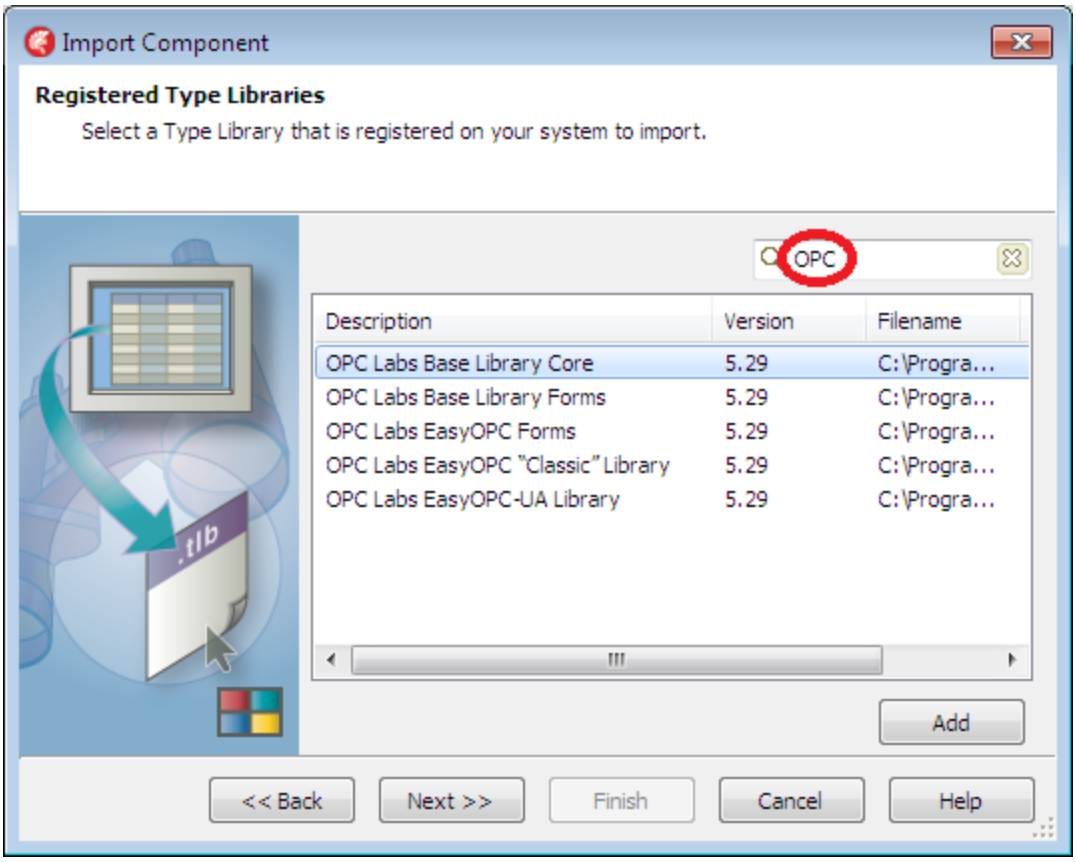
Note, however, that for the purpose of our examples, we already ship Delphi (XE7) components created from importing OPC Data Client type libraries together with the examples. It may be faster and safer to simply reuse them. They are located in the “Imports” subdirectory under the Delphi examples directory (**Examples-COM/OP/Imports** relatively from the OPC Data Client installation folder).

1. In Delphi, select command Component -> Import Component. The first page of the “Import Component” wizardappears, titled “Type of Component”:



Select “Import a Type Library” and press the Next button.

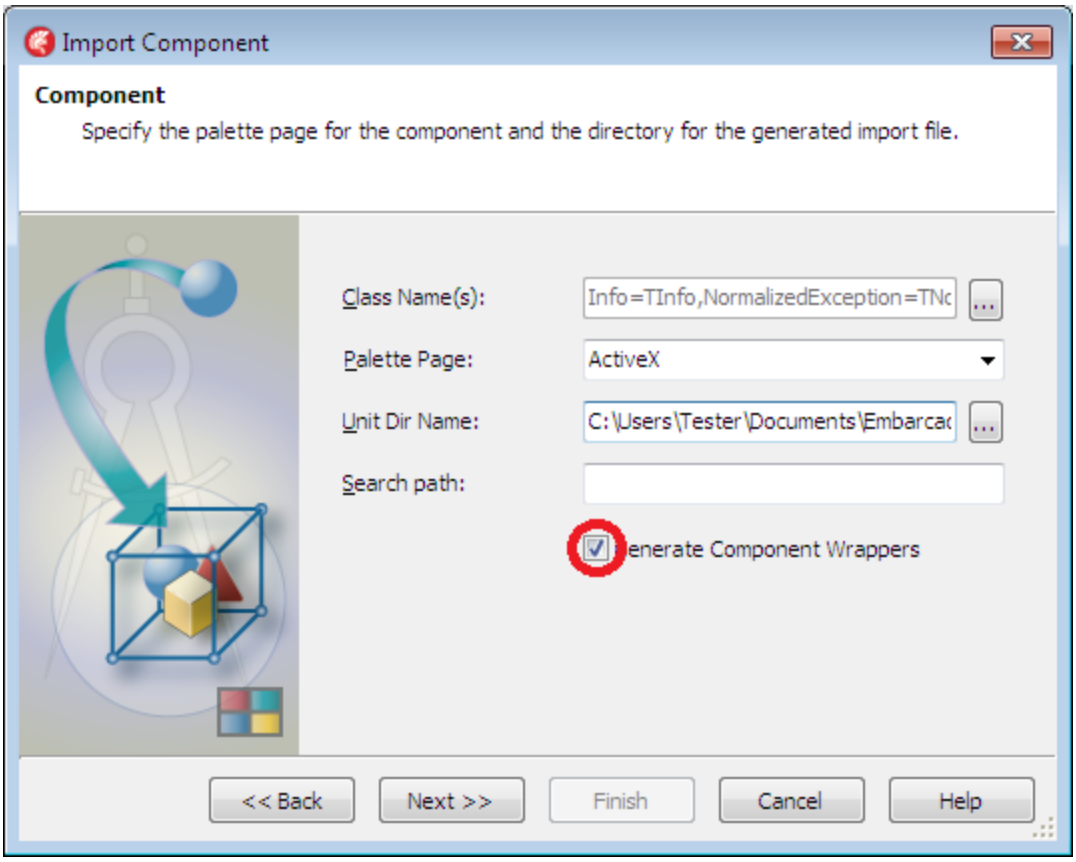
2. The page “Registered Type Libraries” appears:



You may need to resize the form to make it larger, and/or drag the column header dividers to make the columns wider.

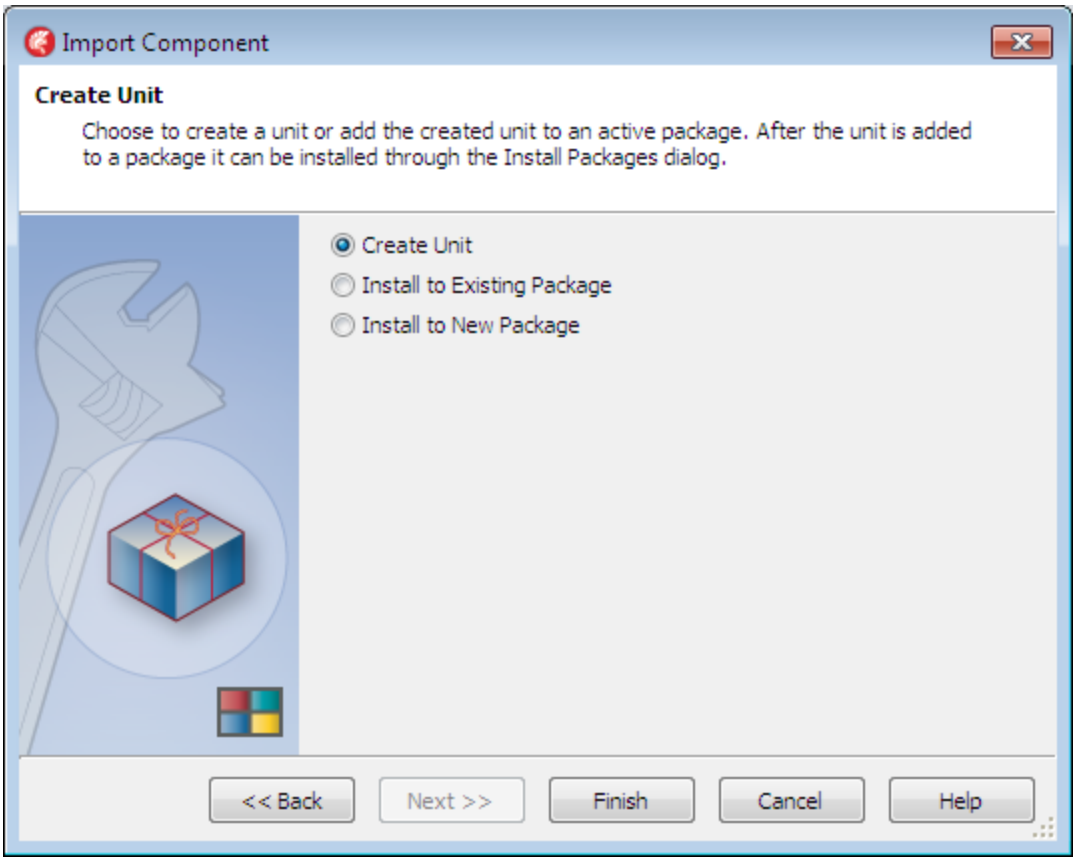
Type “OPC” into the search box, in order to narrow down the list of available type libraries. Select the type library you want to import, and press the Next button.

3. The page “Component” appears:



Check the “Generate Component Wrappers” box, and optionally modify the other settings as needed. Then, press the “Next button”.

4. The page “Create Unit” appears:



Select the option you need (typically, you can leave the "Create Unit" choice selected), and press the Finish button.

5. If you need to import another type library, repeat the process from Step 1.

> ⚠ Note that importing a type library may also silently regenerate (and overwrite) an existing imported component that the type library depends on, but then without the "Generate Component Wrappers" option – potentially messing things up. To avoid this, you can either
>
> a. make backup copies of existing components before importing any new type library, and restore the overwritten components afterwards, if needed; or
> b. import the type libraries in the reverse order of layering, starting with those that are at the top of the hierarchy and proceeding downwards: 1) OPC Labs EasyOPC Forms, 2) and 3) remaining OPC Labs libraries, 4) OPC Labs Base Library Forms and 5) OPC Labs Base Library Core; or
> c. if possible, simply use the pre-imported components that come with our examples, as described above.

4.4.4 Importing Type Libraries in Visual C++

There are several ways to consume the OPC Data Client component in Microsoft Visual C++. One of the easiest is to use the Compiler COM Support. This is done by placing #import directives into your code; the directives reference the OPC Data Client type libraries. The compiler converts the type libraries into C++ header files that describe the COM interfaces.

You can place the #import directives in your code one by one, but you can also simply #include a **QuickOpc.h** file provided with the product in the **SDK\include** subdirectory. This file imports all OPC Data Client type libraries and

declares wrappers for OPC Data Client interfaces and classes. Its content is as follows:

C++

```
// $Header: $
// Copyright (c) CODE Consulting and Development, s.r.o., Plzen. All rights reserved.
// This files imports all QuickOPC libraries (and system libraries they require),
creating Compiler COM Support wrappers.
// It also contains additional definitions for creating event sinks.
#pragma once

// #import system libraries

// mscorlib
#pragma warning(push)
#pragma warning(disable:4278)    // 'ReportEvent': identifier in type library
'BED7F4EA-1A96-11D2-8F08-00A0C9A6186D' is already a macro; use the 'rename' qualifier
#if _MSC_VER >= 1300
#define IMPORT_MSCORLIB "libid:BED7F4EA-1A96-11D2-8F08-00A0C9A6186D"
#else
#define IMPORT_MSCORLIB "mscorlib.tlb"
#endif
#import IMPORT_MSCORLIB
#pragma warning(pop)
using namespace mscorlib;

// System.Drawing
#if _MSC_VER >= 1300

    rename("endpointDescriptor", "EndpointDescriptor") \
    rename("expandedText", "ExpandedText") \
    rename("inputArguments", "InputArguments") \
    rename("inputTypeCodes", "InputTypeCodes") \
    rename("nodeDescriptor", "NodeDescriptor") \
    rename("nodeId", "NodeId") \
    rename("password", "Password") \
    rename("serverCapabilities", "ServerCapabilities") \
    rename("value", "Value")
using namespace OpcLabs_EasyOpcUA;

// OpcLabs.EasyOpcForms
#if _MSC_VER >= 1300
#define IMPORT_OPCLABS_EASYOPCFORMS    "libid:2C654FA0-6CD6-496D-A64E-CE2D2925F388"
#else
#define IMPORT_OPCLABS_EASYOPCFORMS    "OpcLabs.EasyOpcForms.tlb"
```

```
#endif
#import IMPORT_OPCLABS_EASYOPCFORMS
using namespace OpcLabs_EasyOpcForms;

// DISPID-s

// EasyAEClientConfigurationEvents
#define DISPID_EASYAECLIENTCONFIGURATIONEVENTS_LOGENTRY    1001

// EasyAEClientEvents
#define DISPID_EASYAECLIENTEVENTS_EVENTINGFAILURE 1001
#define DISPID_EASYAECLIENTEVENTS_NOTIFICATION 1002

// EasyDAClientConfigurationEvents
#define DISPID_EASYDACLIENTCONFIGURATIONEVENTS_LOGENTRY    1001

// EasyDAClientEvents
#define DISPID_EASYDACLIENTEVENTS_EVENTINGFAILURE 1001
#define DISPID_EASYDACLIENTEVENTS_ITEMCHANGED 1002

// EasyUAClientConfigurationEvents
#define DISPID_EASYUACLIENTCONFIGURATIONEVENTS_LOGENTRY    1001

// EasyUAClientEvents
#define DISPID_EASYUACLIENTEVENTS_DATACHANGENOTIFICATION  1001
#define DISPID_EASYUACLIENTEVENTS_EVENTINGFAILURE  1002
#define DISPID_EASYUACLIENTEVENTS_EVENTNOTIFICATION  1003
#define DISPID_EASYUACLIENTEVENTS_SERVERCONDITIONCHANGED  1004

// EasyUASubscriberEvents
#define DISPID_EASYUASUBSCRIBEREVENTS_DATASETMESSAGE  1001
#define DISPID_EASYUASUBSCRIBEREVENTS_EVENTINGFAILURE  1002
#define DISPID_EASYUASUBSCRIBEREVENTS_RESOLVERACCESS  1003
#define DISPID_EASYUASUBSCRIBEREVENTS_SUBSCRIPTIONRESOLVED  1004
```

The file also makes sure (using the **rename** attributes) that the symbols are properly cased, and adds useful #define-s for defining event sinks.

4.5 Conventions

Conventions

From OPC Labs Knowledge Base
Jump to navigation Jump to search

With the help of various conventions, we try to make it easier to find and discover the information needed, and understand the components' internal consistency.

Contents

Date and Time Conventions

- All OPC-related properties that are of DateTime type (and are consistently in UTC) have corresponding properties with a "Local" postfix, which contain the same value but expressed in local time. For example, DAVtq.Timestamp contains a timestamp in UTC, whereas its DAVtq.TimestampLocal contains the same in local time.

Naming Conventions

Common Naming Conventions

- In OPC-UA, the name part "MonitoredItem" is used wherever the type or member applies to both Data Access and Alarms and Conditions, whereas the names that use the term "DataChange" apply to Data Access only.

Type Names

In addition to being compliant with common Microsoft recommendations for names, and in the .NET part with Microsoft .NET Framework guidelines for names, we follow certain additional naming conventions:

- Types which are specific to very simplified ("easy") model for working with OPC start with the prefix Easy.
- Types which are specific to OPC Data Access start with DA (or EasyDA) prefix, types which are specific to OPC Alarms and Events start with AE (or EasyAE) prefix. Types that are shared among multiple OPC specifications do not have these prefixes.
- Types which are specific to OPC Unified Architecture start with UA (or EasyUA) prefix. Types that are shared among multiple OPC specifications do not have these prefixes.

Note that the second and third conventions work in addition and together with the fact that there are separate DataAccess, AlarmsAndEvents, and UA namespaces for this purpose too.

The above described conventions also give you a bit of hint where to look for a specific type, if you know its name. For example, if the name starts with DA or EasyDA, the type is most likely in the OpcLabs.EasyOpc.DataAccess namespace. Without any special prefix, the type is likely to be in the OpcLabs.EasyOpc or OpcLabs.BaseLib namespace.

Interface Names in COM

As opposed to .NET, every object access in COM is solely made over its interfaces. In COM, after the object is instantiated, you never "see" the object as such – only the interfaces it has. Therefore, at least one additional interface (besides the COM-defined IUnknown and IDispatch) is needed on each .NET exposed to COM.

We consistently use following conventions in COM:

- Incoming interfaces have a form of *_XXXX*, where *XXXX* is the distinguishing part, e.g. _EasyUAClient, for the EasyUAClient object.
- Outgoing interface (for events) have a form of D*XXXX*Events, where *XXXX* is the distinguishing part, e.g.

DEasyUAClientEvents, for the EasyUAClient object.

The incoming interface are dual interfaces. The outgoing interfaces are dispatch-only interfaces, hence the use of 'D' as a prefix.

ProgIDs (COM)

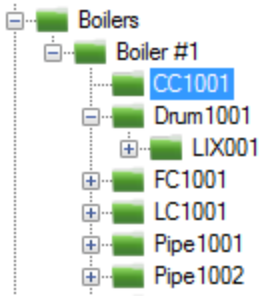
In COM, all our objects have ProgIDs that are identical to their qualified type names in .NET. For example, the main EasyUAClient component resides in the OpcLabs.EasyOpc.UA namespace, and its fully qualified name and therefore also its ProgID is "OpcLabs.EasyOpc.UA.EasyOpcUA". The main EasyDAClient component resides in the OpcLabs.EasyOpc.DataAccess namespace, and its fully qualified name and therefore also its ProgID is "OpcLabs.EasyOpc.DataAccess.EasyOpcDA". This convention makes it easy to instantiate COM objects, based on the namespace-qualified names of their .NET counterparts.

Coloring Conventions

We maintain visual consistency in the product by using specific colors for certain functionality areas. This is typically seen in various icons, images and bitmaps.

Green color is used for OPC Data Access.

For example:



Orange color is used for OPC Alarms&Events.

For example:

Turquoise color is used for OPC Unified Architecture. Because OPC-UA supports multiple functionalities, the turquoise color is sometimes used in combination with other colors, such as green for Data, or orange for Events.

For example:

4.6 Components and Objects

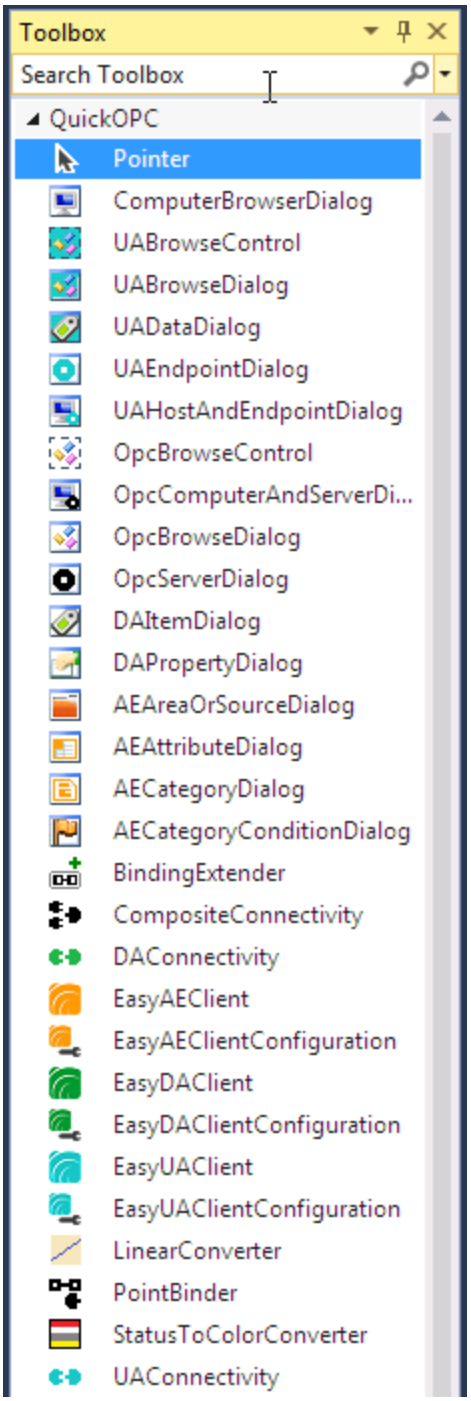
OPC Data Client is a library of many objects. They belong into two basic categories: *Computational objects* provide "plumbing" between OPC servers and your application. They are invisible to the end user. *User interface objects* provide OPC-related interaction between the user and your application.

In This Topic

Components and Objects in .NET Framework

If you are working with an IDE (Integrated Development Environment) such as Visual Studio, the main OPC Data Client components appear in the Visual Studio Toolbox (see example picture below). Note that, however, most OPC Data Client objects can be used directly from the code, and that the Toolbox only offers the components for certain environments, such as Windows Forms; in other environments, you can still use OPC Data Client, but you will instantiate the components directly. Also note that there are many more objects to OPC Data Client than just those classified as designer components and shown on the Toolbox.

The OPC Data Client components in the Toolbox look similar to this:



If, for some reason, some or all of the OPC Data Client components do not appear in the toolbox, see **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

Components and Objects in .NET Standard

In .NET Standard, you instantiate the OPC Data Client objects directly, using the constructs available in the language you are using - for a example, the new keyword in C#, the New keyword in VB.NET, etc.

Components and Objects in COM

In OPC Data Client-COM, the precise way to instantiate the object depends on the programming language you are using. For example:

- In Visual Basic 6.0 and Visual Basic for Applications, if you have referenced the component(s), use the New keyword with the appropriate class name.
- In VBScript (or in VB if you have not referenced the component), use the CreateObject function with the ProgID of the class.
- In JScript, use the 'new ActiveXObject(...)' construct, with the ProgID of the class.
- In C++, create the smart interface pointer passing '__uuidof(...)' to the constructor, using the CLSID of the class.
- In Delphi (Object Pascal), call .Create on the class type create by importing the type library.
- In PHP, use the 'new COM(...)' construct, with the ProgID of the class.
- In Python, use 'win32com.client.Dispatch(...)' construct, with the ProgID of the class.
- In Visual FoxPro, use the CREATEOBJECT function with the ProgID of the class.

4.6.1 Computational Objects

For easy comprehension, there is just one computational object that you need to start with, for each OPC specification:

- For OPC Data Access, it is the EasyDAClient object.
- For OPC Alarms and Events, it is the EasyAEClient object.
- For OPC Unified Architecture, it is the EasyUAClient object.
- For OPC UA PubSub, it is the EasyUASubscriber object.

All other computational objects are helper objects (see further in this chapter). You achieve all OPC computational tasks by calling methods on one of these objects. The remainder of this paragraph describes the use of EasyDAClient object; the steps for EasyAEClient or EasyUAClient object are similar.

In order to be able to use one of these objects, you need to instantiate it first.

In OPC Data Client "Classic" and OPC Data Client-UA, there are two methods that you can use:

- Write the code that creates a new instance of the object, using an operator such as New (Visual Basic), new (Visual C#) or gcnew (Visual C++).
- Drag the component from the Toolbox to the designer surface. This works because they are derived from System.ComponentModel.Component (but is not limited to be used as a "full" component only). You can use this approach in Windows Forms applications, in Console applications and some other types of applications if you first add a designable component to your application. The designer creates code that instantiates the component, assigns a reference to it to a field in the parent component, and sets its properties as necessary. You can then use designer's features such as the Properties grid to manipulate the component.

Note: In addition, there is a static Create() method on each EasyXXClient or EasyXXSubscriber class. This methods works the same as parameterless constructor. For example (in C#), EasyUAClient.Create() is the same as new EasyUAClient().

For OPC Data Client-COM and OPC Data Client-UA for COM, the following table contains information needed to instantiate the objects.

Class Name	CLSID	ProgID

EasyAEClient	3643545B-221F-4960-BF47-8A4DDEC81A67	OpcLabs.EasyOpc.AlarmsAndEvents.EasyAEClient
EasyDAClient	6B0B5307-BCB6-4953-A832-BFCF952F7561	OpcLabs.EasyOpc.DataAccess.EasyDAClient
EasyUAClient	54AFB0EA-9809-4D1D-AFBE-0EC164C59A45	OpcLabs.EasyOpc.UA.EasyUAClient
EasyUASubscriber	EDC1F10E-3FC6-4604-9BC6-4FFF579D271A	OpcLabs.EasyOpc.UA.PubSub.EasyUASubscriber

As described in the "Naming Conventions", in OPC Data Client-COM, all objects have ProgIDs that are identical to their qualified type names in .NET. For example, the ProgID of the main EasyUAClient is therefore "OpcLabs.EasyOpc.UA.EasyOpcUA".

For COM development, CLSIDs of all objects and IIDs of all interfaces can also be found in the Reference documentation (look for the GuidAttribute on the classes and interfaces).

4.6.1.1 Interfaces and Extension Methods

In OPC Data Client.NET, the main methods constituting the functionality of EasyDAClient, EasyAEClient, and EasyUAClient components are actually implementations of IEasyDAClient, IEasyAEClient, and IEasyUAClient interfaces, respectively. The remaining methods and method overloads, which simply build upon the core interface methods, are implemented as extension methods on the interface. Also, at many places, arguments and properties that accept one of the IEasyXXClient interfaces, instead of a concrete component.

In most languages (certainly in C# and Visual Basic), this design leads to the same syntax as if all the methods were implemented directly on the core concrete object. The approach that we hace chosen allows to supply a different implementation of the component's interface where needed, and is currently used for simulation purposes in the browsing controls and dialogs.

4.6.1.2 Isolated Clients and Subscribers

Normally, instances of a client or subscriber object (such as EasyDAClient, EasyAEClient, EasyUAClient) act commonly, sharing the same connections to the target OPC servers (or to the message-oriented middleware, in case of PubSub), and also many common parameters. This way, you can create a large number of these instances and work with them in an easy way, without having to worry about negative effects on the target. If, for example, you create two instances of an EasyDAClient object, and subscribe to some OPC items in each of these instances, only one connection will be created to the OPC server.

This approach works well for most applications, and it allows easy coding in scenarios such as Web development, where each page request may require OPC operations, and the requests may be coming in quick succession and in large numbers, and even processed in parallel.

In some cases, however, you may want to have a dedicated connection to the OPC server, or have more control over the parameters of the connection. In such case, you can set the Isolated property of the EasyXXClient or EasyXXSubscriber object to 'true'. By doing so, operations invoked on this instance of the client object will work with their own connection to the target OPC server, or message-oriented middleware. We say that the client (subscriber) object is *isolated*.

If you create more such isolated client objects, each of them will work with its own connection. Obviously you need to be more careful with this approach, in order to keep the load on the target OPC server in reasonable limits.

4.6.1.3 Shared Instance

Instead of explicitly instantiating the EasyDAClient (or EasyAEClient, EasyUAClient, EasyUASubcriber) objects, you can also use a single, pre-made instance of it, resulting in shorter code. You can access it as a SharedInstance static property on the class, and it contains a default, shared instance of the client object.

Use this property with care, as its usability for larger projects is limited. Its main use is for testing and for non-library application code where just a single instance is sufficient.

If you plan to use events on the EasyXXClient or EasyXXSubscriber component, the shared instance is not suitable for Windows Forms, WPF or similar environments, where a specific SynchronizationContext may be used with each form.

We also do not recommend using the shared instance for library code (if you are developing a Class Library project), due to conflicts that may arise if your library sets some instance parameters which may not be the same as what other libraries or the final application expect.

In OPC Data Client-COM, you can access the shared instance through the EasyXXClientConfiguration (or EasyXXSubscriberConfiguration) object.

4.6.2 User Interface Objects

In OPC Data Client "Classic" and OPC Data Client-UA, you instantiate a user interface object in Windows Forms applications by dragging the appropriate component from the Toolbox to the designer surface. The designer creates code that instantiates the component, assigns a reference to it to a field in the parent component, and sets its properties as necessary. You can then use designer's features such as the Properties grid to manipulate the component.

If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

In OPC Data Client-COM and OPC Data Client-UA for COM, you can use some of the user interface objects (namely, the dialogs – but not the controls) as well. Create the objects as any other OPC Data Client objects on the COM platforms. The convention described earlier (with computational objects) always applies, and therefore the ProgIDs of the user interface objects are the same as the namespace-qualified names of corresponding .NET types.

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

4.6.3 Helper Types

The types described here do not directly perform any OPC operations, but are commonly used throughout OPC Data Client for properties and method arguments.

4.6.3.1 Time Periods

Many method arguments and properties describe time periods, such as update rates, delays, timeouts etc. For

consistency, they are all integers, and they are expressed as number of milliseconds. In OPC UA, an exception to this rule is for the maximum age of value (for reading), which is a floating point number in order to allow a finer precision.

Some method arguments and properties (but only some – see Reference documentation for each method argument or property) allow a special value that represents an "infinite" time period.

In OPC Data Client "Classic" and OPC Data Client-UA, the value for "infinite" time period is equal to Timeout.Infinite (from System.Threading namespace).

Note: Time periods should not be confused with absolute time information, which is usually expressed by means of DateTime structure.

In OPC Data Client-COM, the value for "infinite" time period is equal to -1.

Note: Time periods should not be confused with absolute time information, which is usually expressed by means of Windows DATE data type.

4.6.3.2 Data Objects

The data objects hold the actual data made available by the OPC technology.

4.6.3.2.1 Quality in OPC Classic

OPC Classic represents a quality of a data value by several bit-coded fields. OPC Data Client encapsulates the OPC quality in a DAQuality class. The bit fields in OPC quality are inter-dependent, making it a bit complicated to encode or decode it. The DAQuality type takes care of this complexity. In addition, it offers symbolic constants that represent the individual coded options, and also has additional functionality such as for converting the quality to a string.

The following table attempts to depict the elements of DAQuality and their relations:

<table>
<tr><td colspan="3">DAQuality</td></tr>
<tr><td>property DAQualityChoice QualityChoiceBitField { get; }
property bool IsBad { get; }
property bool IsGood { get; }
property bool IsUncertain { get; }</td><td>SubStatus</td><td rowspan="2">property DALimitChoice LimitBitField { get; set; }</td></tr>
<tr><td colspan="2">property DAStatusChoice StatusBitField { get; set; }
SetQualityAndSubStatus(...)</td></tr>
</table>

You can see that the StatusBitField is actually consisted of QualityChoiceBitField, and a SubStatus. But the semantics of SubStatus is highly dependent on QualityChoiceBitField, and therefore the SubStatus cannot be accessed separately. For the same reason, you cannot directly set the QualityChoiceBitField without providing a value for SubStatus at the same time. Instead, you can call SetQualityAndSubstatus method to modify the two fields at the same time.

Note that OPC Alarms and Events specification "borrows" the quality type from OPC Data Access, and therefore the DAQuality type is used with OPC Alarms and Events as well.

Constants for DAQuality values are contained in the DAQualities enumeration.

4.6.3.2.2 Value, Timestamp and Quality (VTQ) in OPC Classic

The combination of data value, timestamp and quality (abbreviated sometimes as VTQ) is common in OPC. This combination is returned e.g. when an OPC item is read. Note that according to OPC specifications, the actual data value is only valid when the quality is Good or Uncertain (with a certain exception).

OPC Data Client has a DAVtq object for this combination. The object provides access to individual elements of the VTQ combination, and also allows common operations such as comparisons. It can also be easily converted to a string containing textual representation of all its elements.

If you only want a textual representation for a data value from the VTQ, use the DisplayValue method. This is recommended over trying to extract the Value property and converting it to string, as you will automatically receive an empty string if the value is not valid according to OPC rules (e.g. Bad quality), and a null reference case is handled as well.

4.6.3.2.3 Variant Type (VarType) in OPC Classic

In some places in OPC, your code needs to indicate which type of data you expect to receive back, or (in the opposite direction), you receive indication about which type of data certain piece of information is. OPC uses Windows VARTYPE for this (describes a data contained in Windows VARIANT).

OPC Data Client.NET gives you a .NET encapsulation for indicating variant data types, so that you do not have to look up and code in the numeric values of Windows VARTYPE. Instead, wherever you see that a method argument, a property, or other element is of VarType type, you can supply one of the constants defined in the VarTypes enumeration. For example, VarTypes.I2 denotes a 16-bit signed integer, VarTypes.R4 denotes a 32-bit float, and VarTypes.BStr denotes a string. For arrays of values, use constants named VarTypes.ArrayOfXXXX (e.g. VarTypes.ArrayOfI4), or (if the element type is determined in the run time) the VarType.MakeArrayType method.

Note: Microsoft.NET framework contains a similar type, System.Runtime.InteropServices.VarEnum. The types have some similarities, but should not be confused.

OPC Data Client-COM gives you an enumeration for indicating variant data types, so that you do not have to look up and code in the numeric values of Windows VARTYPE. Instead, wherever you see that a method argument, a property, or other element accepts a data type, you can supply one of the constants defined in the VarTypes enumeration. For example, I2 denotes a 16-bit signed integer, R4 denotes a 32-bit float, and BStr denotes a string. For arrays of values, use logical 'or' to combine the element type with the Array constant. Note, however, that the enumeration symbols are only accessible if you reference or import the EasyOPC Type Library, and not all languages and tools are capable of doing it.

4.6.3.2.4 OPC UA Status Code

OPC represents a result of a service or operation in a status code, which consists of several bit-coded fields. OPC Data Client-UA encapsulates the status code in a UAStatusCode class. The bit fields in status code are inter-dependent, making it a bit complicated to encode or decode it. The UAStatusCode type takes care of this complexity. In addition, it offers symbolic constants that represent the individual coded options, and also has additional functionality such as for converting the status code to a string.

The following table attempts to depict the elements of UAStatusCode and their relations, together with related properties and methods:

<table>
<tr><td colspan="6">UAStatusCode
property InternalValue</td></tr>
<tr><td colspan="2">property CodeBits</td><td colspan="4">property FlagBits</td></tr>
<tr><td>property Severity</td><td>property Condition</td><td>property StructureChanged</td><td>property SemanticsChanged</td><td rowspan="2">property InfoType
property HasDataValueInfo</td><td colspan="2">if HasDataValueInfo == true:</td></tr>
<tr><td colspan="4"></td><td>property LimitInfo</td><td>property Overflow</td></tr>
</table>

The CodeBits part represents the numeric value of an error or condition, whereas the FlagBits part provides more information on the meaning of the status code.

OPC Data Client-UA provides a UACodeBits class that contains constants for errors and conditions defined by the OPC-UA specifications. You can compare the resulting CodeBits to the constants if your code needs to look for a specific error or condition.

The semantics of some parts is dependent on InfoType, and therefore the LimitInfo and Overflow properties can only be accessed if the InfoType has a corresponding value, which is indicated by the value of HasDataValueInfo property.

4.6.3.2.5 OPC UA Attribute Data

The combination of data value, source and serve timestamps and status code is common in OPC-UA. This combination is returned e.g. when an attribute of an OPC node is read. Note that according to OPC specification, the actual data value is only valid with certain status codes (typically, when the status is Good).

OPC Data Client-UA has a UAAttributeData object for this combination. The object provides access to individual elements of this combination, and also allows common operations such as comparisons. It can also be easily converted to a string containing textual representation of all its elements.

If you only want a textual representation for a data value from the attribute data, use the DisplayValue method. This is recommended over trying to extract the Value property and converting it to string, as you will automatically receive an empty string if the value is not valid according to OPC rules (e.g. Bad status), and a null reference case is handled as well.

4.6.3.3 Argument Objects

Argument objects are "holders" that contain all arguments necessary to perform certain operation. OPC Data Client has method overrides that accept individual arguments, but also method overrides that accept argument object as an input. The argument object can be reused with other operations without having to specify individual arguments again, and it can also participate in multiple-operation methods where an array of argument objects is accepted on input, and an array of result objects is returned on output.

All argument objects derive from OperationArguments.

4.6.3.4 Result Objects

Result objects are returned by methods that work on multiple elements simultaneously such as EasyDAClient.ReadMultipleItems, or EasyUAClient.ReadMultiple. Such methods return an array of OperationResult objects, or an array of objects derived from OperationResult. This approach is chosen, among other reasons, because the method cannot throw an exception if an operation on a single element fails (as operations on other elements might have succeeded).

Each OperationResult has an Exception property, which indicates the outcome of the operation. If the Exception is a null reference, the operation has completed successfully. There is also a State property, which contains user-defined information that you have passed to the method.

The objects derived from OperationResult have additional properties, which contain the actual results in case the operation was successful. Such objects are e.g. ValueResult (contains a data value), DAVtqResult (contains value, timestamp, and quality combination for OPC "Classic"), or UAAttributeDataResult (contains value, timestamps, and status code combination for OPC-UA).

The OperationResult object (and therefore all result objects derived from it as well) has a Diagnostics property, which contains a collection of warning and informational diagnostics entries gathered, performing the requested operation. You can use this collection to retrieve additional information about the outcome of the operation.

The additional OperationResult.DiagnosticsSummary string contains a textual summary of diagnostics information, one message per line.

Note that diagnostics information in the OperationResult is gathered and available both in case of success, and in case of

a failure.

Currently, the diagnostics information is only available for operations on OPC Unified Architecture (OPC-UA), i.e. not for OPC "Classic".

4.6.3.5 Element Objects

Element objects contain all information gathered about some OPC entity. They are typically returned by browsing methods.

There are following types of element objects for OPC Classic:

- ServerElement object contains information gathered about an OPC Classic (OPC COM or OPC XML) server.
- AEAttributeElement contains information gathered about an OPC Alarms and Events attribute.
- AECategoryElement contains information gathered about an OPC Alarms and Events category.
- AEConditionElement contains information gathered about an OPC Alarms and Events condition.
- AENodeElement object contains information gathered about an OPC node (areas or source in OPC Alarms and Events server's address space).
- AESubconditionElement contains information gathered about an OPC Alarms and Events subcondition.
- DANodeElement object contains information gathered about an OPC node (branch or leaf in OPC Data Access server's address space).
- DAPropertyElement contains information gathered about an OPC Data Access property.

There are following types of element objects for OPC UA:

- UADiscoveryElement object contains information gathered about an OPC-UA application (OPC-UA server).
- UANodeElement object contains information gathered about an OPC node (in OPC server's address space). The node can represent e.g. a branch in the organizing tree of nodes, or a process value, or a property.

Element objects are also returned when you invoke one of the common OPC dialogs for selecting OPC server, OPC-DA item or an OPC-DA property.

4.6.3.6 Descriptor Objects

A *descriptor object* contains information that fully specifies certain OPC entity (but does not contain any "extra" information that is not needed to identify it uniquely). Descriptor objects are used by some method overloads to reduce the number of individual arguments, and to organize them logically.

There are following types of descriptor objects for OPC Classic:

- ServerDescriptor contains information necessary to identify and connect to an OPC Classic server, such as the server's ProgID.
- AENodeDescriptor contains information necessary to identify a node (area or source) in OPC A&E address space, such as Node Id (a string).
- DANodeDescriptor contains information necessary to identify a node (branch or leaf) in OPC DA address space, such as Node Id (a string).
- DAItemDescriptor contains information necessary to identify an OPC item, such as its Item Id, together with additional information such as the data type requested.
- DAPropertyDescriptor contains information necessary to identify an OPC property, such as its Property Id (or a qualified name, in case of OPC XML).

There are following types of descriptor objects for OPC UA:

- UAEndpointDescriptor contains information necessary to identify and connect to an OPC server, such as the server's URL.
- UANodeDescriptor contains information necessary to identify an OPC node in the server, such as the UANodeId that holds the text of its expanded node Id.

Note: For OPC-UA, the meaning of these objects is described further below in chapter "Identifying Information in OPC-UA".

In a ServerDescriptor, the primary means of server identification is the ServerClass property, which contains a string that can hold either ProgID of the server, or its {CLSID}. There are also additional ServerDescriptor properties, all related to the ServerClass property, allowing to individually retrieve or modify parts of the server class designation. The ProgId property contains a ProgID of the server (and is an empty string if the ProgID is not given). The Clsid property contains the CLSID of the server in a form of a Guid (and is Guid.Empty if no CLSID for the server is given). The ClsidString property contains the CLSID string of the server (and is an empty string if no CLSID for the server is given). The ObjectId property contains the object ID, i.e. a ProgID, {CLSID}, or ProgID/{CLSID}.

Each ServerDescriptor is also represented in a string form that uses the URL syntax (e.g. "opcda://127.0.0.1/Kepware.KEPServerEX.V5/{B3AF0BF6-4C0C-4804-A122-6F3B160F4397}"). For more information about these "OPC URLs", see http://www.opclabs.com/resources/developer-blog/1086-a-partial-story-of-opc-urls .

If you have received an element object (e.g. from browsing methods or common OPC dialogs), you can convert it to a descriptor object. In OPC Classic, for example, there is a constructor for ServerDescriptor object that accepts ServerElement as an input, and there is a constructor for DAItemDescriptor object that accepts DANodeElement as an input, too. In OPC UA, there is a constructor for UAEndpointDescriptor object that accepts UADiscoveryElement as an input, and there is a constructor for UANodeDescriptor object that accepts UANodeElement as an input, too.

Nodes and items in OPC address space can be specified using their node Id (or item Id), or using so-called browse paths.

The item Id (or node Id) is a string that uniquely addresses an item (or a node) in OPC address space. Its syntax is determined by the OPC server. It usually consists of the names of nodes used to reach that node from the root of the OPC address space, together with some decorating characters and separators. This is not a requirement, however, and the OPC server may even use item Ids that do not resemble the node names at all. Unless you have detailed knowledge of the particular OPC server you are connecting to, you should not attempt to create item Id strings yourself, from various parts – they should always come from the server. Item Ids (node Ids) are specified by the ItemId property of the DANodeDescriptor or DAItemDescriptor object. Strings convert implicitly to DANodeDescriptor or DAItemDescriptor containing the input string as the value of ItemId property, and you can therefore simply use the string item Ids in place of node and item descriptors.

4.6.3.7 Parameter Objects

Parameter objects are just holders for settings that influence certain aspect of how OPC Data Client works (for example, timeouts). There are several types of parameter objects (such as Timeouts, HoldPeriods, and more). For more information on their details, see the "Setting Parameters" and "Advanced Topics" chapters, and also the Reference documentation.

The parameters of all EasyXXClient objects are consistently organized into three groups:

- SharedParameters (static parameters that are always shared among object instances),
- InstanceParameters (parameters that can always be set independently for each object instance), and
- AdaptableParameters (parameters that are normally shared, but can be made specific to an instance if the Isolated property is set to 'true').

An instance of any EasyXXClient object that is not isolated (i.e. has its Isolated property equal to 'false', which is the default) actually uses following settings:

- Shared parameters from the static property EasyXXClient.SharedParameters,
- adaptable parameters from the static property EasyXXClient.AdaptableParameters, and
- instance parameters from its instance property EasyXXClient.InstanceParameters.

An isolated instance (i.e. an instance which has its Isolated property explicitly set to 'true') of any EasyXXClient object actually uses following settings:

- Shared parameters from the static property EasyXXClient.SharedParameters,
- adaptable parameters from its instance property EasyXXClient.IsolatedParameters, and
- instance parameters from its instance property EasyXXClient.InstanceParameters.

In OPC Data Client.NET, there are sometimes useful conversions and implicit conversions that allow you to easily construct parameter objects. For example, the DAGroupParameters object has a FromInt32 static method, and a corresponding implicit conversion operator, that allow it be constructed from an integer that represents the requested update rate (in milliseconds). This means that in C# and many other languages, you can simply use an integer update rate at all places where DAGroupParameters object is expected, if you are fine with specifying just the update rate and keeping the other properties of DAGroupParameters at their defaults.

All parameter and policy objects (and their constituents) consistently have a static Default property. This allows for a cleaner code where an arguments is needed, but you want to supply a default (there is no need to call the default constructor).

All parameter objects consistently derive from a Parameters base class. This class has a StandardName property (a string). The standard name identifies certain well-known combination of parameter values. When all the parameters correspond to a well-known combination, the StandardName property contains a symbolic name of such combination; otherwise, it contains an empty string. You can also set the StandardName property yourself, and the parameter values will change to reflect the name.

Some other objects that have similar nature also derive from the Parameters base class.

4.6.3.8 Utility Classes

The VarTypeUtilities static class provides a FromType method that allows you to determine the COM-based type VarType (used in OPC operations) that corresponds to a given .NET Type.

The DAUtilities static class provides methods that allow you to determine whether a given data type (VARIANT), percent deadband, update rate or value age are valid values in OPC Data Access.

The AEUtilities static class provides methods that allow you to determine whether given data type (VarType), event severity, event type filter, or notification rate are valid values in OPC Alarms&Events.

4.7 Connection-less Approach

OPC (Client-Server model) is inherently stateful. For starters, connections to OPC servers are long-living entities with rich internal state, and other objects in OPC model such as OPC groups have internal state too. OPC Data Client hides most of the OPC's stateful nature by providing a connection-less (stateless) interface for OPC tasks.

This transformation from a stateful to a stateless model is actually one of the biggest advantages you gain by incorporating OPC Data Client. There are several advantages to a stateless model from the perspective of your application. Here are the most important of them:

- The code you have to write is shorter. You do not have to make multiple method calls to get to the desired state first. Most common tasks can be achieved simply by instantiating an object (needed just once), and making a single method call.
- You do not have to worry about reconstructing all the state after some failure. OPC Data Client reconstructs the OPC state silently in background when needed. This again brings tremendous savings in coding.

The internal state of OPC Data Client components (including e.g. the connections to OPC servers) outlives the lifetime of the individual instances of the main EasyDAClient, EasyAEClient or EasyUAClient object. You can therefore create an instance of this object as many times as you wish, without incurring performance penalty to OPC communications. This characteristic comes extremely handy in programming server-side Web applications and similar scenarios: You can implement your code on page level, and make OPC requests from the page code itself. The OPC connections will outlive the page round-trips (if this was not the case, the OPC server would become bogged down quickly).

4.8 Simultaneous Operations

OPC (Cleint-Server model) works with potentially large quantities of relatively small data items that may change rapidly in time. In order to handle this kind of load effectively, it is necessary to operate on larger “chunks” of data whenever possible. When there is an operation to be performed on multiple elements, the elements should be passed to the operation together, and the results obtained together as well.

In order to ensure high efficiency, your code should allow the same. This is achieved by calling methods that are designed to work on multiple items in parallel. Where it makes sense, OPC Data Client provides such methods, and they contain the work **Multiple** in their names. For example, for reading a value of an OPC item, a method named ReadItemValue exists on the EasyDAClient object (or, ReadValue method on the EasyUAClient object). There is also a corresponding method named ReadMultipleItemValues on the EasyDAClient object (or, ReadMultipleValues on the EasyUAClient object) which can read multiple OPC items at once. It is strongly recommended that you call the methods that are designed for simultaneous operation wherever possible.

Methods for simultaneous operation return an array of OperationResult objects, or its derivatives. Each element in the output array corresponds to an element in the input array with the same index. Some methods or method overloads take multiple arguments, where some arguments are common for all elements, and one of them is the input array that has parts that are different for each element. There is always one method overload that takes a single argument which is an array of OperationArguments objects; this is the most generic method overload that allows each element be fully different from other elements.

4.9 Identifying information in OPC Classic

Nodes in OPC Classic are identified either by Item IDs, or using browse paths.

4.9.1 Browse Paths for OPC Classic

Browse Paths In General

An alternative way (to using a node ID) of specifying a node in OPC address space is using a browse path. The browse path is a sequence of node names, starting from a known location (e.g. the root of the OPC address space). The browse path can also be expressed as a string, where the individual node names are separated by delimiters (e.g. “/”, a slash).

Browse paths can be absolute (starting from a specified node), or relative.

The advantage of the browse paths is that you can construct them yourself, with just knowledge of the node names, without knowing the full node IDs. In the end, each item must be addressed by its node ID, and OPC Data Client will resolve the browse path to a node ID as necessary.

OPC Classic Browse Paths Specifics

In OPC Classic, absolute browse paths always start at the root of the OPC address space, because the root is the only "pre-defined" or well-known node.

An absolute browse path for OPC Classic is contained in a BrowsePath object. Browse paths are commonly specified by the BrowsePath property of the DANodeDescriptor or DAItemDescriptor object.

If a non-null ItemID is specified in the descriptor, OPC Data Client will use this item Id and ignore the browse path. If ItemID is null, OPC Data Client will attempt to resolve the browse path contained in the BrowsePath property of the descriptor. Either item id, or browse path (or both) must be specified.

Besides the ability to get around usage of full node IDs, the other reason to use browse paths is for OPC browsing with OPC Servers that only support OPC Data Access 1.0 specification. Such OPC servers cannot start the browsing at a node in the address given just by its Item ID; the node must always be reached by browsing from the root level. If the ID of such node it already known, OPC Data Client takes care of supplying the proper browse path automatically, but this cannot be always done. If, however, a browse path is given (which can be done by using the DANodeElement that is the output of the browsing to construct the DANodeDescriptor that is the input of further browsing), the browsing can proceed normally.

4.9.1.1 OPC Classic Browse Path Format

In OPC Classic, the slash at the beginning of the browse path denotes an absolute path that starts from the root of the OPC address space. The string form of a browse path is a concept on the client side (OPC Data Client), and does not appear in OPC specifications.

A browse path can be represented by a string; in such case, it can express either a relative or absolute browse path (the BrowsePath object cannot hold relative browse paths).

As mentioned above, the format of the browse path string is such that the individual node names are separated by slashes ("/"). The slash at the beginning of the browse path denotes an absolute path that starts from the root of the OPC address space. In addition, '.' denotes a current level, and '..' denotes a parent level, similarly to the conventions used in Windows file system.

Because the node names can contain any characters, we need to consider situations in which the node name itself contains a slash ('/') or a dot ('.'). In such case, in the string format of browse paths, these characters are escaped by preceding them with an ampersand ('&'). An ampersand itself needs to be escaped, too.

4.10 Identifying information in OPC XML

OPC Data Client.NET supports the OPC XML-DA specification transparently, with the same objects that are used for COM-based OPC Data Access. The two specifications are quite similar, and for most part, developers will not see much difference. Accesses to OPC-DA and OPC XML-DA can be freely mixed, even in the same method call. This transparency has been achieved by several generalizations in the object model and API.

OPC XML-DA specification identifies certain entities differently. The specifics of those are explained further below.

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

4.10.1 OPC XML Servers

In OPC XML, a client connects to a server with the use of the server URL. OPC Data Client uses the ServerDescriptor class for identifying servers, and you can construct a ServerDescriptor by passing it a string that contains the server URL. The URL is also accessible in the UrlString property of the ServerDescriptor, and there is an implicit conversion available from a (URL) string to a ServerDescriptor. This means that at most places in OPC Data Client API, you can specify an OPC XML server simply by using its URL.

URLs of OPC XML servers can start with "http:", "https:", or "opc.xmlda" (which is internally treated as "http:").

For compatibility between OPC COM and OPC XML, the ServerDescriptor (which, for COM, contained mainly the machine name and server class in the past) is generalized to be able to describe both COM and XML based servers. The primary information in the ServerDescriptor is its UrlString. For OPC COM servers, the URL is composed in such a way that it contains the original Location (i.e. machine name) and ServerClass properties. For OPC XML servers, their URL can be used as the UrlString directly.

Note: We use the term "location" when we need to describe either a "machine name" (used in COM) or a "host name" (used with the Web, and OPC XML).

The ServerDescriptor also contains an additional NetworkSecurity property. This object can optionally specify the network credentials used when connecting to an OPC XML server.

The ServerElement (returned when you browse for OPC servers) has a UrlString property that can be used to connect to OPC XML servers.

4.10.2 OPC XML Nodes and Items

OPC XML-DA does not identify OPC items by a single string as OPC COM. Instead, it uses an additional string, and only the combination of the two identifies an item in an OPC XML-DA server. The original string that roughly corresponds to OPC item ID is called "ItemName" in the OPC XML-DA specification; in OPC Data Client, we use the existing ItemId property for it. The additional string is called "ItemPath" in the OPC XML-DA specification; in OPC Data Client, we have introduced a NodePath property for it. This property appears both in the DANodeDescriptor and DANodeElement. When you use the information received from the OPC XML browsing, both ItemId and NodePath are filled in the DANodeElement, and you can easily convert it to a DANodeDescriptor and it will "just work". If you are getting the nodes (items) from elsewhere, you need to create a DANodeDescriptor that contains both these strings (at least in general case; some OPC XML-DA server do not use them both).

4.10.3 OPC XML Properties

OPC XML-DA identifies properties by a string (a XML qualified name), instead of the numerical code used in OPC COM. For this a reason, a DAPropertyDescriptor and a DAPropertyElement have an additional QualifiedName property. When the component returns the DAPropertyElement from browsing, it fill is the information it knows about. When you pass the DAPropertyDescriptor to the component, you can fill in either PropertyId, or QualifiedName, or both. The component will use whatever is available and at the same time usable by the underlying technology. For the most common case, standard

(well-known) properties can always be identified using their numerical ID, and the component will look up their qualified name automatically.

The DAPropertyElement (returned when you browse for OPC properties) contains an additional ItemPath property for OPC XML. For properties coming from OPC XML servers, if the property can be accessed as an item as well, the property is filled in with the string that together with the ItemId identifies the OPC item that corresponds to the OPC property.

4.11 Identifying Information in OPC UA (Client-Server)

These chapters explain how the most commonly used entities in OPC Unified Architecture, such as servers, nodes, and attributes, are identified in the application code.

Note: Some entities in OPC Unified Architecture are identified by URIs and URLs. .NET Framework has a System.Uri class that provides an object representation of a uniform resource identifier (URI) and easy access to the parts of the URI. It is generally recommended that programs use this class for URI manipulation internally, instead of working with plain strings containing URIs. In OPC Unified Architecture, however, the URIs and URLs are used in such a way that they do not always have to fully conform to the specifications. For this reason, URI and URL arguments and properties in OPC Data Client-UA are also strings and not System.Uri (and are consistently named so they contain "**UriString**" or "**UrlString**").

4.11.1 OPC UA Server Endpoints

A Server Endpoint is a physical address available on a network that allows clients to access one or more services provided by a server. Server endpoint is specified by its URL string.

Besides standard URLs e.g. with HTTP scheme, OPC Unified Architecture uses its own schemes, such as "opc.tcp". Examples of server endpoint URL strings are:

- http://opcua.demo-this.com:51211/UA/SampleServer
- opc.tcp://opcua.demo-this.com:51210/UA/SampleServer
- http://localhost:51211/UA/SampleServer
- opc.tcp://localhost:51210/UA/SampleServer

Note: For backward compatibility, it is also possible to use "opc.http:" in place of "http:" scheme in OPC UA endpoint descriptors (for OPC Unified Architecture over SOAP/HTTP). You should not, however, use "opc.http:" in new projects.

In OPC Data Client-UA, server endpoint corresponds to a UAEndpointDescriptor object that you create and pass to various methods. An implicit conversion from a string containing the URL of the endpoint exists. It is therefore common to specify UAEndpointDescriptor-s simply as strings, relying on the implicit conversion.

Endpoint Selection Policy

A single OPC-UA server may have multiple endpoints with the same functionality, but using different protocols, or different security settings, and expose the list of its own endpoint using discovery services. By default, the component will attempt to interpret the server endpoint you have specified as server's discovery endpoint, and automatically select the best endpoint.

How precisely the endpoint is selected is determined by Endpoint Selection Policy (UAEndpointSelectionPolicy object) that you can parameterize in the SessionParameters property on the EasyUAClient object. Such parameterization has a global effect. You can also specify the endpoint selection policy individually for just a specific endpoint descriptor. To do so, set the EndpointSelectionPolicy Property of the UAEndpointDescriptor to a non-null instance of UAEndpointSelectionPolicy. For details, see **OPC UA Endpoint Selection Policy (Section 4.11.1.1)**.

User Identity

If a user authentication is required by the OPC UA server, you can specify user identity on the endpoint, in the UAEndpointDescriptor object (alternatively, it can be specified in session parameters - the token infos from these two places are effectively merged together). See **User Identity in QuickOPC-UA (Section 5.1.2.6.1)** for more detailed discussion of this topic.

In order to make specifying the user identity with an endpoint descriptor easy OPC Data Client has extension methods on the UAEndpointDescriptor class. They are:

- WithAnonymousIdentity Method
- WithKerberosIdentity Method
- WithUserNameIdentity Method
- WithX509CertificateIdentity Method

These methods return a copy of the endpoint descriptor with the specified token info in its user identity.

4.11.1.1 OPC UA Endpoint Selection Policy

The OPC UA Endpoint Selection Policy allows you to specify the criteria that OPC Data Client will use when picking up the endpoint from those made available by the target OPC UA server.

In This Topic

Purpose

Why do we need the endpoint selection policy, with so many settings it has? Wouldn't it be better to specify the endpoint precisely, the same way as many other products do?

The answer to this is that in some cases, specifying the endpoint precisely may be possible and suitable. This is when you do know the endpoint parameters upfront, and you are sure that it will not change in the future. OPC Data Client actually supports this as well (using the very same endpoint selection policy mechanism, and specifying precise parameters).

In most cases, however, the aim of the client applications written with OPC Data Client is to be flexible, and be able to connect to the target server not just now, but even in future, when the details of the communication may change. This can happen easily, for example, when certain encryption algorithm becomes outdated, and the server is updated to no longer support it (or to give it less preference). If you had hard-coded the precise endpoint parameters into the client application, the solution will stop working at this point, and the client application will have to be rebuilt (or reconfigured, if you had allowed for that). With endpoint selection policy properly specified to indicate your intent, the client application written with OPC Data Client will automatically select the endpoint that uses the newer encryption algorithm, without anybody having to rewrite or reconfigure it.

If you use the endpoint selection policy just to express what you want to achieve, instead of picking the precise parameters which may change in future, you make your application more flexible and robust. Doing it this way is in line

with the declarative approach used wherever possible in OPC Data Client - that is, you express what you want to achieve, and leave the how of actually doing it to the component.

Effective Endpoint Selection Policy

The endpoint selection policy which is actually used for a concrete connection is called *effective endpoint selection policy*. It is determined in following steps:

1. If the EndpointSelectionPolicy Property on the UAEndpointDescriptor is set to a non-null value, this policy will be used.
2. Otherwise, if the Isolated Property on the EasyUAClient is true, the policy from EasyUAClient.IsolatedParameters.SessionParameters.EndpointSelectionPolicy will be used.
3. Otherwise (if the Isolated Property on the EasyUAClient is false, which is the default), the policy from static EasyUAClient.AdaptableParameters.SessionParameters.EndpointSelectionPolicy will be used.

Endpoint Selection Algorithm

When OPC Data Client selects an endpoint, it first decides whether each of the endpoints provided by the server is eligible for selection, using the effective endpoint selection policy. Settings in the Filter category (see further down) can influence this process.

The endpoint is then selected from those that have passed the filtering. What constitutes the "best" endpoint is determined by settings in the Order category (see further down).

Finally, some of the selected endpoint parameters may be modified, mainly for security reasons. This part is influenced by the settings in the Transform category (see further down).

Settings Category: Filter

Settings in this category influence which endpoints are eligible for selection. You can specify a subset of settings, and depending on how you do it, the filter may allow multiple endpoints, or just one. In some cases, the settings may conflict, and the policy would then not be able to select any endpoint ever.

Precise endpoint selection

You can specify a precise endpoint by setting following three properties of the endpoint selection policy:

- AllowedMessageSecurityModes Property
- SecurityPolicyUriString Property
- TransportProfileUriString Property

More details to the values of these properties are given below.

The AllowedMessageSecurityModes property of the UAEndpointSelectionPolicy gives you a possibility to completely enable or disable certain classes of endpoints from selection, based on their security mode. You can combine the value of this property from following flags:

- SecurityNone: No security is applied.
- SecuritySign: All messages are signed but not encrypted.
- SecuritySignAndEncrypt: All messages are signed and encrypted.

The UAEndpointSelectionPolicy.SecurityPolicyUriString property, when not an empty string (empty string is the default), specifies the required security policy URI string of the endpoint. This allows the developer to select the precise security policy, when so required. The static UASecurityPolicyUriStrings class contains strings that can be used to specify the security policy URI.

The TransportProfileUriString Property (when not an empty string) specifies the required transport profile of the endpoint. The static UATransportProfileUriStrings Class contains strings that can be used to specify the transport profile URI.

Imprecise endpoint selection

The endpoint does not have to be specified precisely. You can leave one or more of the settings described under "Precise endpoint selection" above - for example, keep the SecurityPolicyUriString Property and/or the TransportProfileUriString Property empty. Or, you can use combinations of multiple flags in the AllowedMessageSecurityModes Property. There are also pre-defined symbolic values for combinations of these flags, such as All (which is the default setting), or Secure.

If you want to specify some aspects of the transport profile, but not the precise transport profile as such, you can use:

ProtocolName Property: When not empty, requires the endpoint to use the specified protocol. Valid values are e.g. "HTTP", "HTTPS" or "TCP".

DataEncodingName Property: When not empty, requires that the endpoint uses the specified data encoding. Valid values are e.g. "Binary" and "XML".

Additional properties that influence the endpoint selection are:

- AllowZeroSecurityLevel Property. Endpoints that the server marks with a zero security level are not recommended, and are only made available for backward compatibility. This property determines whether such endpoints will be allowed.
- RejectObsoleteSecurityPolicies Property. Some security policies are already known to be obsolete. This property determines whether endpoints that use an obsolete security policy will be rejected.

The mechanism described here allows you to describe the intended capabilities of the endpoint, but without specifying its configuration precisely. This is the recommended approach, because it has a built-in flexibility to cover changes in server configuration or version, protocol improvements etc. An alternative approach (described above) allows more precision, but does not adapt so well to changes in server configuration.

Requiring security objectives

Following the declarative approach, you may decide to simply state which security objectives you want to achieve, using following properties:

- RequireAuthentication Property. Specifies whether authentication of the communication parties is required.
- RequireConfidentiality Property. Specifies whether communication confidentiality is required (usually provided by encryption).
- RequireIntegrity Property. Specifies whether communication integrity is required (usually provded by signing).

The communication parameters are considered as a whole. For example, even when the OPC UA message security does not provide encryption, the encryption may be provided by the transport. This is the case e.g. with the transports based on the HTTPS protocol.

Requiring certain security objectives may be combined with other settings in the policy.

Settings Category: Order

When more than one endpoint passes the filtering, settings in the Order category influence which of these endpoints will get selected. The endpoint are given a numerical ranking, and the endpoint will the highest ranking will become the winner. The basis for the ranking is the security level of each endpoint, as indicated by the server itself. The security level can then optionally be further manipulated.

The MessageSecurityPreference property of the UAEndpointSelectionPolicy tells the component whether endpoints that provide message security are preferred for selection. It has three possible values:

- Negative: The endpoints without message security will be given a major preference. This is the default setting, for good interoperability.
- None: The endpoint security level provided by the server will be followed without change.
- Positive: The endpoints with message security will be given a major preference.

Settings Category: Transform

Settings in this category influence how the endpoint parameters are modified after the endpoint has been selected. The available settings are:

- EnforceSamePort Property: When enabled, replaces the port number in the selected endpoint by the value used for discovery.
- EnforceSameSite Property: When enabled, replaces the host name in the selected endpoint by the value used for discovery.

The modifications are done mainly for security reasons.

Predefined Endpoint Selection Policies

Instead of setting the individual parameters of the policy, you can also use one of the predefined policies provided by the component. They are made available by static properties on the UAEndpointSelectionPolicy Class. They are:

- NoMessageSecurity Property. Endpoint selection policy that allows only connections with no message security.
- Default Property. Default endpoint selection policy. Allows all kinds of connections, and prefers connections with no message security.
- GuaranteedIntegrity Property. Endpoint selection policy that guarantees communication integrity.
- GuaranteedIntegrityExcludingObsolete Property. Endpoint selection policy that guarantees integrity, excluding obsolete security policies.
- GuaranteedIntegrityAndConfidentiality Property. Endpoint selection policy that guarantees integrity and confidentiality, excluding obsolete security policies.
- FullySecured Property. An endpoint selection policy that guarantees integrity, confidentiality and authentication, with additional safeguards.

Alternatively, parameters of the policy object can be changed to one these predefined policies by settings its StandardName Property to one of the names listed above. This is useful e.g. on the COM platform, where static properties do not exist.

4.11.1.2 Preselected vs. Synthetised Endpoints

> ⚠ This is an advanced topic. You do not need to study it unless you have a specific need.

In This Topic

When OPC Data Client establishes a connection to an OPC UA server, it tries to do so in most effective manner. When necessary, it first calls the GetEndpoints service of the target OPC UA server, and *preselects* the endpoint. In other cases, the call to GetEndpoints can be skipped, and the endpoint is *synthetised* by OPC Data Client.

The endpoint demands preselection if at least of one the conditions below is fulfilled:

- Your target development platform is .NET Standard.
- The AllowedMessageSecurityModes Property in the effective endpoint policy does not specify a precise (single) message security mode.
- The SecurityPolicyUriString Property is empty (i.e. does not specify a precise security policy URI).
- The AllowedMessageSecurityModes is not equal to SecurityNone, or the SecurityPolicyUriString is not equal to None ("http://opcfoundation.org/UA/SecurityPolicy#None"), and at the same time, the server certificate is not given in the ServerCertificate Property (or ServerCertificateByteArray Property) of the UAEndpointDescriptor.

This might seem quite complicated, but it boils down to a simple rule: If OPC Data Client has information available that is precise enough to allow connection without calling GetEndpoints first, it will connect straight away, if supported by the underlying OPC UA stack (= endpoint synthesis). Otherwise, it will call GetEndpoints in order to obtain the list of available endpoints and select from them (= endpoint preselection).

In addition, the endpoint will be preselected if you set the AlwaysPreselectEndpoint Property to true.

Preselected Endpoints

Endpoint preselection is performed by calling the OPC UA GetEndpoints service on the target server, and applying the effective endpoint selection policy to it. The OPC UA server must therefore properly support the GetEndpoints service for endpoint preselection to work. When applying the endpoint selection policy yields an endpoint, the parameters of it are then used to create the OPC UA secure channel.

Synthetised Endpoints

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

Synthetised endpoints do not require use of the OPC UA GetEndpoints service as part of the connection process. They are therefore a bit faster to connect, and (more importantly) allow connections even to servers that do not support the GetEndpoints service (or do not support it properly). The client code in OPC Data Client simply uses the parameters from the effective endpoint selection policy when creating the OPC UA secure channel. The effective endpoint selection policy is then applied to the endpoints returned by the OPC UA server from the CreateSession service, and OPC Data Client checks whether the endpoint specified by the policy is available.

> ⚠ Some servers may have endpoint URLs that are different from the discovery endpoint URL, or differ depending on the security policy. For example, a server built with OPC Foundation .NET legacy stack and using the HTTP protocol will use an endpoint URL with appended "/None" for its insecure endpoint. You need to specify the precise URL of the specific endpoint, for the synthesized endpoint to work.

4.11.1.3 Server Certificate in Endpoint Descriptor

> ⚠ This is an advanced topic. You do not need to study it unless you have a specific need.

If you want the endpoint be synthetised and not preselected (see **Preselected vs. Synthetised Endpoints (Section 4.11.1.2)**) and you want the communication be secure, you must also present a server certificate. This is done using the ServerCertificate Property (or the ServerCertificateByteArray Property) in the UAEndpointDescriptor.

4.11.2 OPC UA Node IDs

Node ID is an identifier for a node in an OPC server's address space.

OPC Unified Architecture allows the OPC server to choose one or more types of node IDs for representation of its nodes. Node IDs can be numeric (a 32-bit integer), string, a GUID (globally unique identifier, 128 bits), or opaque (a binary data blob).

OPC Data Client-UA works with so-called expanded node IDs, which contain the node's identifier together with a complete namespace URI. A single server may contain nodes in multiple namespaces, and the server maintains a namespace table where each namespace can be identified by an index. During a communication session with an OPC client, nodes are identified using indices into the namespace table. The namespace table contents and order of elements may, however, change between sessions.

OPC Data Client-UA does not expose node IDs with indices into a namespace table alone. Instead, it always passes around the complete URI string of a namespace with a node ID. Because this expanded form of a node ID is used, a Node ID in OPC Data Client-UA is stable between sessions, and can also be persistent (stored) and later used without a complexity of additional index remapping.

Depending on the type of Node ID, the expanded node ID string may have one of the following forms:

- nsu=*namespaceUri*;i=*integer*
- nsu=*namespaceUri*;s=*string*
- nsu=*namespaceUri*;g=*guid*
- nsu=*namespaceUri*;b=*base64string*

In OPC Data Client-UA, an expanded node ID corresponds to UANodeId object that you create and pass to various methods. An implicit conversion from a string containing the expanded text of Node ID exists. It is therefore common to specify UANodeId-s simply as strings, relying on the implicit conversion. Also note that UANodeId is usually a part of UANodeDescriptor and can be (implicitly) converted to it easily.

When the UANodeId object contains no data, it is considered a null Node Id, and its IsNull property is true. Beware that this is different from having a null reference to a UANodeId (which, in most places, is not allowed).

> In OPC Data Client, when formatting the expanded text of OPC UA Node IDs and qualified names, the namespace URI (the text after "nsu=") is separated with an additional space from the following semicolon, allowing the URI be easily separated by tools that are not aware of the specific syntax of OPC UA Node IDs and qualified names. Similarly, any trailing whitespace in the namespace URI part (the text after "nsu=") is ignored when parsing the OPC UA Node IDs and qualified names.

Note: During browsing, the OPC server provides so-called browse names (browse IDs), which can be combined into browse paths. The browse names (browse IDs) usually "look" more user- friendly and you may be tempted to think that they would be more appropriate for node identification. The purpose of browse names (browse IDs) is, however, different,

and using them alone for node identification would be inefficient, and sometimes ambiguous.

There are many ways in which you can construct node IDs, depending on which information you have available.

Following examples are intended to show you many of the options that exist for constructing the node IDs.

C#

```
// This example shows different ways of constructing OPC UA node IDs.

using System;
using OpcLabs.BaseLib;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace;
using OpcLabs.EasyOpc.UA.AddressSpace.Parsing;
using OpcLabs.EasyOpc.UA.AddressSpace.Parsing.Extensions;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._UANodeId
{
    class _Construction
    {
        // A node ID specifies a namespace (either by an URI or by an index), and an
identifier.
        // The identifier can be numeric (an integer), string, GUID, or opaque.
        public static void Main1()
        {

            // A node ID can be specified in string form (so-called expanded text).
            // The code below specifies a namespace URI (nsu=...), and an integer
identifier (i=...).
            UANodeId nodeId1 = new UANodeId("nsu=http://test.org/UA/Data/;i=10853");
            Console.WriteLine(nodeId1);

            // Similarly, with a string identifier (s=...).
            UANodeId nodeId2 = new
UANodeId("nsu=http://test.org/UA/Data/;s=someIdentifier");
            Console.WriteLine(nodeId2);

            // Actually, "s=" can be omitted (not recommended, though)
            UANodeId nodeId3 = new
UANodeId("nsu=http://test.org/UA/Data/;someIdentifier");
            Console.WriteLine(nodeId3);
            // Notice that the output is normalized - the "s=" is added again.

            // Similarly, with a GUID identifier (g=...)
            UANodeId nodeId4 = new UANodeId("nsu=http://test.org/UA/Data/;g=BAEAF004-
1E43-4A06-9EF0-E52010D5CD10");
            Console.WriteLine(nodeId4);
            // Notice that the output is normalized - uppercase letters in the GUI are
converted to lowercase, etc.
```

```
            // Similarly, with an opaque identifier (b=..., in Base64 encoding).
            UANodeId nodeId5 = new UANodeId("nsu=http://test.org/UA/Data/;b=AP8=");
            Console.WriteLine(nodeId5);

            // Namespace index can be used instead of namespace URI. The server is
allowed to change the namespace
            // indices between sessions (except for namespace 0), and for this reason,
you should avoid the use of
            // namespace indices, and rather use the namespace URIs whenever possible.
            UANodeId nodeId6 = new UANodeId("ns=2;i=10853");
            Console.WriteLine(nodeId6);

            // Namespace index can be also specified together with namespace URI. This
is still safe, but may be
            // a bit quicker to perform, because the client can just verify the
namespace URI instead of looking
            // it up.
            UANodeId nodeId7 = new
UANodeId("nsu=http://test.org/UA/Data/;ns=2;i=10853");
            Console.WriteLine(nodeId7);

            // When neither namespace URI nor namespace index are given, the node ID is
assumed to be in namespace
            // with index 0 and URI "http://opcfoundation.org/UA/", which is reserved
by OPC UA standard. There are
            // many standard nodes that live in this reserved namespace, but no nodes
specific to your servers will
            // be in the reserved namespace, and hence the need to specify the
namespace with server-specific nodes.
            UANodeId nodeId8 = new UANodeId("i=2254");
            Console.WriteLine(nodeId8);

            // If you attempt to pass in a string that does not conform to the syntax
rules,
            // a UANodeIdFormatException is thrown.
            try
            {
                UANodeId nodeId9 = new
UANodeId("nsu=http://test.org/UA/Data/;i=notAnInteger");
                Console.WriteLine(nodeId9);
            }
            catch (UANodeIdFormatException nodeIdFormatException)
            {
                Console.WriteLine($"*** Failure {nodeIdFormatException.Message}");
            }

            // There is a parser object that can be used to parse the expanded texts of
node IDs.
            UANodeIdParser nodeIdParser10 = new UANodeIdParser();
            UANodeId nodeId10 =
nodeIdParser10.Parse("nsu=http://test.org/UA/Data/;i=10853");
            Console.WriteLine(nodeId10);
```

```
            // The parser can be used if you want to parse the expanded text of the
node ID but do not want
            // exceptions be thrown.
            UANodeIdParser nodeIdParser11 = new UANodeIdParser();
            IStringParsingError stringParsingError =
                nodeIdParser11.TryParse("nsu=http://test.org/UA/Data/;i=notAnInteger",
out UANodeId nodeId11);
            if (stringParsingError == null)
                Console.WriteLine(nodeId11);
            else
                Console.WriteLine($"*** Failure: {stringParsingError.Message}");

            // You can also use the parser if you have node IDs where you want the
default namespace be different
            // from the standard "http://opcfoundation.org/UA/".
            UANodeIdParser nodeIdParser12 = new
UANodeIdParser("http://test.org/UA/Data/");
            UANodeId nodeId12 = nodeIdParser12.Parse("i=10853");
            Console.WriteLine(nodeId12);

            // The namespace URI string (or the namespace index, or both) and the
identifier can be passed to the
            // constructor separately.
            UANodeId nodeId13 = new UANodeId("http://test.org/UA/Data/", 10853);
            Console.WriteLine(nodeId13);

            // You can create a "null" node ID. Such node ID does not actually identify
any valid node in OPC UA, but
            // is useful as a placeholder or as a starting point for further
modifications of its properties.
            UANodeId nodeId14 = new UANodeId();
            Console.WriteLine(nodeId14);

            // Properties of a node ID can be modified individually. The advantage of
this approach is that you do
            // not have to care about syntax of the node ID expanded text.
            UANodeId nodeId15 = new UANodeId();
            nodeId15.NamespaceUriString = "http://test.org/UA/Data/";
            nodeId15.Identifier = 10853;
            Console.WriteLine(nodeId15);

            // The same as above, but using an object initializer list.
            UANodeId nodeId16 = new UANodeId
            {
                NamespaceUriString = "http://test.org/UA/Data/",
                Identifier = 10853
            };
            Console.WriteLine(nodeId16);
```

```
            // If you know the type of the identifier upfront, it is safer to use typed
properties that correspond
            // to specific types of identifier. Here, with an integer identifier.
            UANodeId nodeId17 = new UANodeId();
            nodeId17.NamespaceUriString = "http://test.org/UA/Data/";
            nodeId17.NumericIdentifier = 10853;
            Console.WriteLine(nodeId17);

            // Similarly, with a string identifier.
            UANodeId nodeId18 = new UANodeId();
            nodeId18.NamespaceUriString = "http://test.org/UA/Data/";
            nodeId18.StringIdentifier = "someIdentifier";
            Console.WriteLine(nodeId18);

            // Similarly, with a GUID identifier.
            UANodeId nodeId19 = new UANodeId();
            nodeId19.NamespaceUriString = "http://test.org/UA/Data/";
            nodeId19.GuidIdentifier = Guid.Parse("BAEAF004-1E43-4A06-9EF0-

```
Rem This example shows different ways of constructing OPC UA node IDs.

Option Explicit

' A node ID specifies a namespace (either by an URI or by an index), and an identifier.
' The identifier can be numeric (an integer), string, GUID, or opaque.

Const UANodeClass_All = 255

' A node ID can be specified in string form (so-called expanded text).
' The code below specifies a namespace URI (nsu=...), and an integer identifier
(i=...).
' Assigning an expanded text to a node ID parses the value being assigned and sets all
corresponding
' properties accordingly.
Dim NodeId1: Set NodeId1 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId1.ExpandedText = "nsu=http://test.org/UA/Data/;i=10853"
WScript.Echo NodeId1

' Similarly, with a string identifier (s=...).
Dim NodeId2: Set NodeId2 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId2.ExpandedText = "nsu=http://test.org/UA/Data/;s=someIdentifier"
WScript.Echo NodeId2
```

```
' Actually, "s=" can be omitted (not recommended, though)
Dim NodeId3: Set NodeId3 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId3.ExpandedText = "nsu=http://test.org/UA/Data/;someIdentifier"
WScript.Echo NodeId3
' Notice that the output is normalized - the "s=" is added again.

' Similarly, with a GUID identifier (g=...)
Dim NodeId4: Set NodeId4 = CreateObject("OpcLabs.EasyOpc.UA.AddressSpace.UANodeId")
NodeId4.ExpandedText = "nsu=http://test.org/UA/Data/;g=BAEAF004-1E43-4A06-9EF0-
E52010D5CD10"
WScript.Echo NodeId4
' Notice that the output is normalized - uppercase letters in the GUI are converted to
lowercase, etc.

' Similarly, with an opaque identifier (b=..., in Base64 encoding).

4.11.2.1 Namespace indices in Node Ids

During most communication between the client and the server, OPC Unified Architecture uses namespace indices, which are integer numbers, to distinguish between namespaces. The namespaces indices reference a namespace table made available by the server, and only the namespace table actually contains the namespace URIs. The order of entries in the server's namespace table can change between sessions. For this reason, namespace indices should not be persisted, as they alone are not generally sufficient to identify a namespace and thus a node.

There are, however, situations where you may want to include the namespace index in the expanded node Id string:

- For optimization. If the namespace index is given, it may be slightly faster to reference the node.
- Sometimes the party you are working with does not fully understand the consequences of using a namespace index, and only gives you node Ids with the namespace indices, without the namespace URIs.

For situations like this, OPC Data Client-UA allows the use of "ns=..." notation for a namespace index inside the expanded node ID strings, and has two additional provisions:

- When expanded node ID strings are provided out of OPC Data Client-UA components, they contain BOTH the namespace URI, and the namespace index. For example, the browsing may return following expanded node ID string to you:

  ```
  nsu=http://test.org/UA/Data/;ns=2;i=10219
  ```

- When OPC Data Client-UA receives an expanded node ID string on input, it uses the namespace URI specified in

the string by the “nsu=…” notation, if present. If the namespace URI is not present, a namespace index, specified by the “ns=…” notation (or defaulted to zero), is used. If both the namespace URI and the namespace index are present, semantically it always behaves the same as if only the namespace URI was specified, but the namespace index may be used for performance optimization. This means that the expanded node ID strings provided out of the component always refer to nodes through the namespace URI, even if they (in addition) contain the namespace index.

Note that namespace index 0 (zero) is reserved for the standard namespace maintained by the OPC Foundation ("http://opcfoundation.org/UA/"), and is not usually specified inside the expanded node ID strings. In addition (as an exception to the rule laid out above), it is safe to use nodes inside namespace index 0 without specifying their namespace URI, because the namespace index is "tied" to the URI by the provision in the standard, and the OPC servers are not allowed to change that.

4.11.2.2 Standard Node IDs

OPC Data Client-UA provides static classes with standard Node IDs defined by OPC Foundation: UADataTypeIds, UAMethodIds, UAObjectIds, UAObjectTypeIds, UAReferenceTypeIds, UAVariableIds, and UAVariableTypeIds. You can use properties of these static classes to easily specify “well-known” nodes you need to refer to, for example, the “ObjectsFolder” node which is a common starting node for browsing.

There are following classes with standard Node IDs for OPC-UA:

- UADataTypeIds: A class that declares constants for all Data Types in the Model Design. This class contains definitions for nodes such as BaseDataType, Number, Integer, Boolean, and so on.
- UAMethodIds: A class that declares constants for all MethodIds. in the Model Design.This class contains definitions for method nodes for condition handling, status machine handling, and others.
- UAObjectIds: A class that declares constants for Objects in the Model Design. This class contains definitions for folder nodes such as DataTypesFolder, EventTypesFolder, ObjectsFolder, ObjectTypesFolder, ReferenceTypesFolder, RootFolder, Server, TypesFolder, VariableTypesFolder, ViewsFolder, and others.
- UAObjectTypeIds: A class that declares constants for Object Types in the Model Design. This class contains definitions for nodes such as BaseObjectType, FolderType, and many other object types.
- UAReferenceTypeIds: A class that declares constants for Reference Types in the Model Design. This class contains definitions for nodes such as Aggregates, HasChild, HasComponent, HasProperty, HierarchicalReferences, Organizes, and more.
- UAVariableIds: A class that declares constants for all Variables in the Model Design.
- UAVariableTypeIds: A class that declares constants for all Variable Types in the Model Design.

When you need to pass a standard node to any method, simply use the corresponding property from the static class, such as UAObjectIds.ObjectsFolder.

4.11.3 OPC UA Qualified Names

In OPC-UA, the qualified name comprises of a namespace, and a text portion (a name). The qualified name is used, for example, as browse name (i.e. it is one of the information pieces that you obtain for a node when browsing nodes in the OPC-UA address space). In the opposite direction (from your application to the server), qualified names are used in OPC-UA browse paths, to specify the target node of each element in the browse path.

In This Topic

OPC Data Client-UA has a UAQualifiedName object for representing the qualified names. You can access individual parts of the qualified name by corresponding properties on this object (namely, the NamespaceUriString and Name properties). The ExpandedText property contains a string that fully specifies the qualified name, borrowing a syntax used for expanded node IDs described in an earlier article (except that in this case, the “identifier” part is always of a string type).

> In OPC Data Client, when formatting the expanded text of OPC UA Node IDs and qualified names, the namespace URI (the text after "nsu=") is separated with an additional space from the following semicolon, allowing the URI be easily separated by tools that are not aware of the specific syntax of OPC UA Node IDs and qualified names. Similarly, any trailing whitespace in the namespace URI part (the text after "nsu=") is ignored when parsing the OPC UA Node IDs

> and qualified names.

Standard qualified names

OPC Data Client-UA provides a static class with standard qualified names defined by OPC Foundation: UABrowseNames. You can use properties of this static class to easily specify “well-known” browse names you need to refer to. For example, the “SessionsDiagnosticsSummary” browse name is defined by the UABrowseNames.SessionsDiagnosticsSummary property, and you can pass the value of this property to any method that expects UAQualifiedName on input.

4.11.3.1 Namespace indices in qualified names

During most communication between the client and the server, OPC Unified Architecture uses namespace indices, which are integer numbers, to distinguish between namespaces. The namespaces indices reference a namespace table made available by the server, and only the namespace table actually contains the namespace URIs. The order of entries in the server’s namespace table can change between sessions. For this reason, namespace indices should not be persisted, as they alone are not generally sufficient to identify a namespace and thus a qualified name.

There are, however, situations where you may want to include the namespace index in the expanded qualified name string:

- For optimization. If the namespace index is given, it may be slightly faster to reference the qualified name.
- Sometimes the party you are working with does not fully understand the consequences of using a namespace index, and only gives you qualified names with the namespace indices, without the namespace URIs.

For situations like this, OPC Data Client-UA allows the use of “ns=…” notation for a namespace index inside the expanded qualified name strings, and has two additional provisions:

- When expanded qualified name strings are provided out of OPC Data Client-UA components, they contain BOTH the namespace URI, and the namespace index. For example, the browsing may return following expanded qualified name string to you:

  ```
  nsu=http://test.org/UA/Data/;ns=2;s=Data
  ```

- When OPC Data Client-UA receives an expanded qualified name string on input, it uses the namespace URI specified in the string by the “nsu=…” notation, if present. If the namespace URI is not present, a namespace index, specified by the “ns=…” notation (or defaulted to zero), is used. If both the namespace URI and the namespace index are present, semantically it always behaves the same as if only the namespace URI was specified, but the namespace index may be used for performance optimization. This means that the expanded qualified name strings provided out of the component always refer to qualified names through the namespace URI, even if they (in addition) contain the namespace index.

Note that namespace index 0 (zero) is reserved for the standard namespace maintained by the OPC Foundation ("http://opcfoundation.org/UA/"), and is not usually specified inside the expanded qualified name strings.

4.11.4 Browse Paths in OPC-UA

Browse Paths In General

An alternative way (to using a node ID) of specifying a node in OPC address space is using a browse path. The browse path is a sequence of node names, starting from a known location (e.g. the root of the OPC address space). The browse path can also be expressed as a string, where the individual node names are separated by delimiters (e.g. "/", a slash).

Browse paths can be absolute (starting from a specified node), or relative.

The advantage of the browse paths is that you can construct them yourself, with just knowledge of the node names, without knowing the full node IDs. In the end, each item must be addressed by its node ID, and OPC Data Client will resolve the browse path to a node ID as necessary.

OPC UA Browse Paths Specifics

In OPC Unified Architecture, each element of the browse path is not a simple string, but instead, it is a structured object (UABrowsePathElement) which contains more information that allows identifying the child node.

The OPC-UA browse path element contains a qualified name of the child node (a name qualified with a namespace URI), in the UABrowsePathElement.TargetName property. This allows ensuring the uniqueness of browse path elements in complex OPC-UA servers, such as when the address space is aggregated from multiple sources.

Because in OPC-UA there may be various references that lead from the parent node to a child node, the OPC-UA browse paths need to specify which type of reference should be used. This is done by the UABrowsePathElement.ReferenceTypeId property; in addition, it is possible to specify whether the reference should be followed in reverse direction (UABrowsePathElement.ReferenceIsInverse), and whether subtypes of the given reference type should also be considered.

An absolute browse path for OPC-UA is contained in a UABrowsePath object. The starting node of an OPC-UA browse path is contained in the UABrowsePath.StartingNodeId property. Browse paths are commonly specified by the BrowsePath property of the UANodeDescriptor object.

The UABrowsePath can be a null browse path, in case its StartingNodeId is a null node ID. A null browse path is used to specify that no browse path is known or given. Note that passing a null browse path object is different from passing a null reference to UABrowsePath (which is not allowed in most places).

If a non-null NodeId is specified in the descriptor, OPC Data Client will use this node Id and ignore the browse path. If NodeId is null, OPC Data Client will attempt to resolve the browse path contained in the BrowsePath property of the descriptor. Either node ID, or browse path (or both) must be specified.

4.11.4.1 OPC UA Browse Path Elements

OPC UA browse path elements are represented by UABrowsePathElement objects. Each browse path element has following data members:

- ReferenceTypeId Property. The type of reference (an instance of UANodeId Class) to follow from the current node. The current path cannot be followed any further if the reference type is not available on the node instance.
- ReferenceIsInverse Property. Indicates whether the inverse Reference should be followed.
- IncludeSubtypes Property. Indicates whether subtypes of the ReferenceType should be followed.
- TargetName Property. The browse name of the target node (an instance of UAQualifiedName Class).

The UABrowsePathElement has various constructor overloads with different combinations of these parameters. In addition, there are static methods on the UABrowsePathElement Class that allow you to easily create commonly used browse path elements:

- The Create Method creates a new OPC-UA browse path element with given reference type and target name, for following in forward direction, and including subtypes.

- The CreateInverse Method creates a new OPC-UA browse path element with given reference type and target name, for following in inverse direction, and including subtypes.
- The CreateSimple Method creates a new OPC-UA browse path element with given target name, and specifying any hierarchical forward reference.
- There are static methods for creation of browse path elements for all standard *concrete* references, taking just the target name as input. For example, the HasProperty Method creates a browse path element for following a specific HasProperty reference in a forward direction.

The created browse path elements can then be added to a UABrowsePathElementCollection Class, forming a relative path.

4.11.4.2 OPC-UA Browse Path Format

In This Topic

OPC Data Client-UA uses the relative browse path string format recommended by the OPC specification, but extends it by an ability to specify the starting node ID (and therefore introducing the absolute browse paths), and by an ability to specify the namespaces not by an index into a namespace table, but by a namespace URI. The precise syntax of these extensions is beyond the current scope of this document, and the description below is just a close approximation.

An OPC-UA browse path can be represented by a string; in such case, it can express either a relative or absolute browse path (the UABrowsePath object cannot hold relative browse paths).

As mentioned above, the format of the browse path string is such that the individual elements (usually, node names) are separated by delimiters. In OPC-UA, the delimiter actually precedes every element, i.e. there is a delimiter also at the beginning of the relative browse path. Different delimiters are available for specifying various reference types. Following delimiters are available:

Delimiter	Description
/	Follow any subtype of HierarchicalReferences (technically, numerical node Id 44 in namespace 0).
.	Follow any subtype of Aggregates reference type (technically, numerical node Id 33 in namespace 0). This is stricter than '/'.
<referenceSpecifier>	Follow the specified reference type. A '#' placed in front of the reference type name indicates that subtypes should not be followed. A '!' in front of the reference type name is used to indicate that the inverse reference should be followed.

If the OPC-UA browse path does not start with any of the above delimiters, it denotes an absolute path that starts from the node specified at the beginning of the string. For example, "[Objects]/Boilers" is an example of such absolute OPC-UA browse path, whereas "/Boilers" in OPC-UA is a relative browse path.

The string form of an OPC-UA browse path is a concept on the client side (OPC Data Client), and the browse paths strings are not directly processed by OPC-UA servers.

Because the node names can contain any characters, we need to consider situations in which the node name itself contains a slash ('/') or a dot ('.'). In such case, in the string format of browse paths, these characters are escaped by preceding them with an ampersand ('&'). An ampersand itself needs to be escaped, too.

Parsing

Parsing an absolute browse path:

C#

```
// Parses an absolute  OPC-UA browse path and displays its starting node and elements.

using System;
using OpcLabs.EasyOpc.UA.Navigation;
using OpcLabs.EasyOpc.UA.Navigation.Parsing;

namespace UADocExamples._UABrowsePathParser
{
    class Parse
    {
        public static void Main1()
        {
            var browsePathParser = new UABrowsePathParser();
            UABrowsePath browsePath;
            try
            {
                browsePath = browsePathParser.Parse("
[ObjectsFolder]/Data/Static/UserScalar");
            }
            catch (UABrowsePathFormatException browsePathFormatException)
            {
                Console.WriteLine("*** Failure: {0}",
browsePathFormatException.GetBaseException().Message);
                return;
            }

            // Display results
            Console.WriteLine("StartingNodeId: {0}", browsePath.StartingNodeId);

            foreach (UABrowsePathElement browsePathElement in browsePath.Elements)
                Console.WriteLine(browsePathElement);

            // Example output:
            // StartingNodeId: ObjectsFolder
            // /Data
            // /Static
            // /UserScalar
        }
    }
}
```

Object Pascal

```
// Parses an absolute  OPC-UA browse path and displays its starting node and elements.

class procedure Parse.Main;
var
  BrowsePath: _UABrowsePath;
  BrowsePathElement: _UABrowsePathElement;
  BrowsePathParser: OpcLabs_EasyOpcUA_TLB._UABrowsePathParser;
  Count: Cardinal;
  Element: OleVariant;
```

```
  ElementEnumerator: IEnumVariant;
begin
  BrowsePathParser := CoUABrowsePathParser.Create;

  try
    BrowsePath := BrowsePathParser.Parse('[ObjectsFolder]/Data/Static/UserScalar');
  except
    on E: EOleException do
    begin
      WriteLn(Format('*** Failure: %s', [E.GetBaseException.Message]));
      Exit;
    end;
  end;

  // Display results
  WriteLn('StartingNodeId: ', BrowsePath.StartingNodeId.ToString);

  WriteLn('Elements:');
  ElementEnumerator := BrowsePath.Elements.GetEnumerator;
  while (ElementEnumerator.Next(1, Element, Count) = S_OK) do
  begin
    BrowsePathElement := IUnknown(Element) as _UABrowsePathElement;
    WriteLn(BrowsePathElement.ToString);
  end;

  // Example output:
  // StartingNodeId: ObjectsFolder
  // Elements:
  // /Data
  // /Static
  // /UserScalar

end;
```

PHP

```
// Parses an absolute  OPC-UA browse path and displays its starting node and elements.

$BrowsePathParser = new
COM("OpcLabs.EasyOpc.UA.Navigation.Parsing.UABrowsePathParser");

try
{
    $BrowsePath = $BrowsePathParser->Parse("[ObjectsFolder]/Data/Static/UserScalar");
}
catch (com_exception $e)
{
    printf("*** Failure: %s\n", $e->getMessage());
    exit();
}

// Display results
printf("StartingNodeId: %s\n", $BrowsePath->StartingNodeId);

printf("Elements:\n");
```

```
for ($i = 0; $i < $BrowsePath->Elements->Count; $i++)
{
    printf("%s\n", $BrowsePath->Elements[$i]);
}

// Example output:
// StartingNodeId: ObjectsFolder
// Elements:
// /Data
// /Static
// /UserScalar
```

VB.NET

```
' Parses an absolute  OPC-UA browse path and displays its starting node and elements.

Imports OpcLabs.EasyOpc.UA.Navigation
Imports OpcLabs.EasyOpc.UA.Navigation.Parsing

4.11.5 OPC UA Attribute IDs

Attribute is a primitive characteristic of a Node. All Attributes are defined by OPC UA, and may not be defined by clients or servers (i.e. the attribute set is not vendor-extensible). Attributes are the only elements in the address space permitted to have data values.

In most cases, you will probably be working with the Value attribute, which contains the actual value of a variable. If you need to address a different attribute, use the UAAttributeId enumeration, which contains constants for all attribute IDs available in OPC UA address space.

UAAttributeId can be given as AttributeId property of the UAAttributeArguments object (and derived objects, such as UAReadArguments, UAWriteArguments, UAWriteValueArguments, and EasyUAMonitoredItemArguments). You can then pass this object to a corresponding method on the main EasyUAClient object.

4.11.6 OPC UA Index Range Lists

OPC Unified Architecture has support for single- and multidimensional arrays in data values. In addition, it is also possible to work with (read, write, subscribe to) only a subset of an array, so that the whole (potentially large) array does not have to be transferred between the OPC server and OPC client.

OPC Data Client-UA uses Index Range Lists (UAIndexRangeList objects) to control which parts of array value should be accessed. An index range list can be used to identify the whole array, a single element of a structure or an array, or a single range of indexes for arrays. Index Range List is basically a list of individual Index Ranges (UAIndexRange objects), each containing a range for a single dimension of an array.

There is an implicit conversion from an integer (Int32) to a UAIndexRange, so if your language (such as C#) supports implicit conversions, an index range containing just a single element can be written simply as the element index, without explicitly constructing the UAIndexRange object.

Besides constructing the UAIndexRangeList from individual UAIndexRange objects, it is also possible to specify the index range list by parsing a string, using static UAIndexRangeList.TryParse method.

Examples of index range strings:

- 5:20
- 10:11,1:2

- 1,4:7,90

Dimensions are separated by commas. A minimum and maximum value, separated by a colon, denotes a range of index. If the colon is missing, only a single for an index is selected. An empty string denotes the whole array.

One-dimensional index range lists can be easily constructed using the UAIndexRangeList.OneDimension static method, passing it either the single index, or minimum and maximum indices.

UAIndexRangeList can be given as IndexRangeList property of the UAAttributeArguments object (and derived objects, such as UAReadArguments, UAWriteArguments, UAWriteValueArguments, and EasyUAMonitoredItemArguments). You can then pass this object to a corresponding method on the main EasyUAClient object.

4.12 Identifying information in OPC UA PubSub

There are two aspects, or levels, to identifying information in OPC UA PubSub.

The actual information being exchanged relies on **OPC UA PubSub physical identifiers (Section 4.12.1)**. Example of these are publisher Ids and dataset writer Ids. The physical identifiers are those that are actually used to establish connections with the message-oriented middleware, and are those that appear in the network messages transmitted by publishers and received by subscribers. Some physical identifiers are always needed at certain point - without them, OPC UA PubSub cannot work.

OPC UA PubSub also has a configuration model (which can reside in OPC UA Server or in a file), and the configuration model provides logical identifiers (mainly, names) for PubSub objects. The logical identifiers (**OPC UA PubSub logical identifiers (Section 4.12.2)**) are easier to work with for humans, and the configuration model has a hierarchical structure which makes it better to comprehend. The use of logical identifiers also allows the higher levels to accommodate to changes, because they provide a mapping mechanism and "shield" the consumers from the physical details. For example, a dataset writer Id (which is an integer) may change due to configuration changes, but as long as the consumer refers to the dataset writer using its logical name (which does not change), the communication can still be established without a problem. The use of this extra logical level is, however, entirely optional, and depends on the consuming application.

OPC Data Client provides way to work with either identifiers, and combines them together into **OPC UA PubSub Descriptors (Section 4.12.3)**. The transformation from logical to physical identifiers is done "behind the scenes" using a process known as **OPC UA PubSub logical resolution (Section 5.1.5.1.4)**.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

4.12.1 OPC UA PubSub physical identifiers

This article describes the physical identifiers used in OPC UA PubSub communication. For a distinction between physical and logical identifiers, see **Identifying information in OPC UA PubSub (Section 4.12)**.

In This Topic

Network Address and Resource Address

Network address is an abstract concept used to represent the basic information needed to make a PubSub connection to the message oriented middleware. In OPC Data Client, it represented by the NetworkAddress Class. The network address specifies a network interface used for the communication, with its InterfaceName Property. This is an empty string if you want to leave the choice of the network interface up to the component, or a non-empty string specifying the name of the network interface on the computer where the component runs.

Resource address is a concrete derivation of network address, in which the network address information is represented by a resource string - essentially, a URL string. Currently, all network addresses used in OPC UA PubSub are resource

addresses. In OPC Data Client, resource address is represented by the ResourceAddress Class. The actual URL information is stored in its ResourceDescriptor Property.

URL schemes and syntaxes

The URL schemes and syntaxes for OPC UA PubSub are described in OPC specifications. The ones currently supported by core OPC Data Client are:

- opc.udp://<host>[:<port>]
- opc.eth://<host>[:<VID>[.PCP]]

With UDP, both IPv4 and IPv6 addresses are supported.

> OPC Data Client supports Enhanced Host Name Resolution in OPC UA PubSub URLs. This allows you to conveniently and reliably use some pre-defined host names as shortcuts for IP and MAC addresses with the above URL schemes, such as "ip6-allrouters" or "eth-broadcast".

OPC Data Client will, by default, use MQTT protocol with any of the URL schemes below:

- mqtt:
- mqtts:
- ssl:
- tcp:
- ws:
- wss:

The details of the URL syntax are then left on the concrete MQTT communication package used (see MQTT communication packages). Some communication packages define useful extensions to the URL syntax, which are described with each communication package. The basic syntax options, described in the OPC UA PubSub specification, are supported by every communication (as long as the corresponding scheme is supported at all), i.e.:

- mqtts://<domain name>[:<port>][/<path>]
- mqtt://<domain name>[:<port>][/<path>]
- wss://<domain name>[:<port>][/<path>]

Publisher Id

The publisher Id is a unique identifier for a publisher with the message-oriented middleware. A publisher can use a publisher Id of one of these types:

- Byte (8-bit unsigned integer)
- UInt16 (16-bit unsigned integer)
- UInt32 (32-bit unsigned integer)
- UInt64 (64-bit unsigned integer)
- String

> Publisher Ids are only equal if both their type and their value are equal. For example, a UInt16 publisher Id with value 31 is different from UInt32 publisher Id with the same value. You therefore need to be careful when specifying the publisher Ids, and with numerical Ids, pay attention to their precise type. Also, a String publisher Id is different from any numerical publisher Id, even if it carries a string representation of the same numerical value (such as a string "31", in our example).

In OPC Data Client, the publisher Id is represented by the UAPublisherId Class, and the types of publisher Ids are expressed by the UAPublisherIdType Enumeration. The easiest way to create a publisher Id is to use one of the static CreateXXXX methods, defined on the class:

- CreateByte Method
- CreateUInt16 Method
- CreateUInt32 Method
- CreateUInt64 Method
- CreateString Method

In a **Message Filtering (OPC UA PubSub) (Section 5.1.5.1.2)**, you can also use a publisher Id with type None. This specifies that no filtering on publisher Ids should be performed.

Writer Group Id

The writer group Id is an unsigned 16-bit integer that identifies the writer group. It is unique across writer groups for a publisher Id. Writer groups can only have non-zero Ids, but a zero writer group Id may be used in a **Message Filtering (OPC UA PubSub) (Section 5.1.5.1.2)** to specify that no filtering on writer group Ids should be performed.

Dataset Writer Id

The dataset writer Id identifies the dataset writer in the writer group. It is an unsigned 16-bit integer that is unique across all dataset writers for a publisher Id. Dataset writers can only have non-zero Ids, but a zero dataset writer Id may be used in a **Message Filtering (OPC UA PubSub) (Section 5.1.5.1.2)** to specify that no filtering on dataset writer Ids should be performed.

Field Name and Field Index

Each dataset consists of a collection of dataset fields. Each field has a unique name within a dataset. Some message mappings (such as JSON) transfer the field names in the dataset message, others (such as UADP) do not, and they rely on the order of fields, which then must be the same as in the dataset metadata.

When OPC Data Client delivers information to you, it preferably uses field names, but it resorts to field indexes when the field names are not available. When you need to specify a dataset field to OPC Data Client, you can use either form (name or index). Normally, we recommend using field names and not field indexes, but an exception must be made in case when message mapping such as UADP is sued, and metadata (as a source of field names) is not available).

Dataset Metadata (OPC UA PubSub) (Section 5.1.5.1.3) can be provided through **OPC UA PubSub logical resolution (Section 5.1.5.1.4)**, or you can supply it manually (from the code).

4.12.2 OPC UA PubSub logical identifiers

The logical identifiers allow PubSub objects be found in the PubSub configuration.

PubSub Connection Name, Writer Group Name,

In This Topic

and DataSet Writer Name

A PubSub configuration contains a collection of PubSub connections, and each PubSub connection is identified by its name, which is a string. For publishers, a PubSub connection determines the physical publisher Id that is used by that publisher.

A PubSub connection contains a collection of writer groups, and each writer group is also identified by its name (a string). Each writer group has its physical writer group Id specified.

A writer group contains a collection of dataset writers, and each dataset writer is also identified by its name (a string). Each dataset writer has its physical dataset wroiter Id specified.

Published Dataset Name

In a PubSub configuration, each published dataset has a unique name (a string). Published datasets may be organized in a tree of (named) dataset folders. The name of published dataset, however, must still be unique across the whole PubSub configuration, not just in its dataset folder.

A dataset writer may be associated with a published dataset by means of published dataset name.

4.12.3 OPC UA PubSub Descriptors

This article describes the descriptors used in OPC UA PubSub communication. For a relation between physical and logical identifiers and descriptors, see **Identifying information in OPC UA PubSub (Section 4.12)**.

In This Topic

Explanation of Terms

In order to be able to describe how OPC Data Client handles the logical and physical identifiers, especially in relation to **OPC UA PubSub logical resolution (Section 5.1.5.1.4)**, we need to define some terms first. There are also properties and methods that use these terms in their names, so knowing what they mean is beneficial to understand their purpose.

We say that a descriptor or filter *strictly physical* when it does not have a logical identifier in itself - that is, the name of the PubSub object is empty - and all its constituent descriptors (if there are any) are also strictly physical.

We say that a descriptor or filter *requires resolution* when an access to PubSub configuration is necessary in order to interpret the information in it for PubSub communication purposes. For example, a PubSub connection descriptor requires resolution when it has no (physical) network address specified, but it has a (logical) non-empty connection name. Similarly, a writer group descriptor requires resolution when its dataset writer Id is set to zero (i.e. "unknown"), but it has a (logical) non-empty dataset writer name, and so on.

A *physicalization* of a descriptor or filter is an operation that makes it strictly physical. A physicalization is only possible on descriptor or filters that currently do not require resolution. Physicalization is performed by setting the logical name of the object to an empty string, and physicalizing its constituent descriptors (if there are any).

PubSub Connection Descriptor

A PubSub connection descriptor combines together:

- Logical name of the connection (optional)
- Physical network address (optional)
- Connection transport parameters
- Transport profile URI

In order to specify a PubSub connection, you can set the PubSub connection name, or its network address, or both.

> The PubSub connection can be "redirected" so that it uses a packet capture file, instead of true connection to the message oriented middleware (network). This is useful in all kinds of troubleshooting and development tasks. Such redirection is performed by setting up the PubSub connection descriptor in a specific way. For more information, see **Using packet capture files with OPC UA PubSub (Section 14.3)**.

Writer Group Descriptor

A writer group descriptor combines together an optional logical writer group name with an optional writer group Id. That is, in order to specify a writer group, you can set the writer group name, or its Id, or both.

Dataset Writer Descriptor

A dataset writer descriptor combines together an optional logical dataset writer name with an optional dataset writer Id. That is, in order to specify a dataset writer, you can set the dataset writer name, or its Id, or both.

Subscribe Dataset Filter

The subscribe dataset filter is a kind of compound descriptor. It is documented separately in **Message Filtering (OPC UA PubSub) (Section 5.1.5.1.2)**.

4.13 Security

In this part of the documentation:

- **OPC UA Security (Client-Server) (Section 4.13.1)**

4.13.1 OPC UA Security (Client-Server)

OPC Unified Architecture is designed as secure solution from the ground up. The result is a solid, secure infrastructure that can be, at the same time, complex to understand, and sometimes difficult to deploy and configure properly.

Security in OPC UA is a broad subject that we cannot and will not cover in detail here. It is recommended that you study available materials. Here are some useful links that can get you started:

- Secure communication with IEC 62541 OPC UA: https://opcfoundation.org/wp-content/uploads/2014/05/OPC-

UA_Security_EN.pdf
- The OPC UA Security Model For Administrators: https://opcfoundation.org/wp-content/uploads/2014/05/OPC-UA_Security_Model_for_Administrators_V1.00.pdf

OPC Data Client-UA attempts to simplify the security configuration where possible, but a reasonable level of understanding OPC-UA security is still needed.

4.13.1.1 Providing OPC UA Client Instance Certificate

Similarly to server instance certificate checking described above, in a secured OPC-UA solution, the OPC client identifies itself to the OPC server using its own instance certificate. The OPC server authenticates the certificate and checks whether the communication with that OPC client is authorized. Typically, the process of checking other party's instance certificate is achieved through use of certificate trust lists, accessible programmatically and by means of UA Configuration Tool (installed with our product, and with OPC-UA downloads provided by OPC Foundation).

Since with OPC Data Client-UA you are developing an OPC-UA client application, this client application must therefore typically provide its instance certificate to the OPC servers it is connecting to. OPC Data Client-UA attempts to make this process easier by automatically selecting parameters for the certificate, and if the certificate does not exist yet, by creating it and storing into the appropriate certificate store on the computer. Depending on your deployment scenario, you may also create the certificate and put it into the certificate store by some other means, and in that case, you would simply let OPC Data Client-UA use that certificate.

VBScript

```
Rem This example demonstrates how to set the application name for the client certificate.

Option Explicit

' The configuration object allows access to static behavior.
Dim ClientConfiguration: Set ClientConfiguration =
CreateObject("OpcLabs.EasyOpc.UA.EasyUAClientConfiguration")
WScript.ConnectObject ClientConfiguration, "ClientConfiguration_"

' Set the application name, which determins the subject of the client certificate.
' Note that this only works once in each host process.
ClientConfiguration.SharedParameters.EngineParameters.ApplicationParameters.ApplicationName
= "QuickOPC - VBScript example application"

' Do something - invoke an OPC read, to trigger some loggable entries.
Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.UA.EasyUAClient")
On Error Resume Next
Dim value: value = Client.ReadValue("http://opcua.demo-this.com:51211/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=10853")
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0

' The certificate will be located or created in a directory similar to:
' C:\Users\All Users\OPC Foundation\CertificateStores\UA Applications\certs\
' and its subject will be as given by the application name.

WScript.Echo "Processing log entry events for 10 seconds..."
WScript.Sleep 10*1000

' Event handler for the LogEntry event.
' Print the loggable entry containing client certificate parameters.
Sub ClientConfiguration_LogEntry(Sender, e)
    If e.EventId = 161 Then WScript.Echo e
End Sub
```

The type and location of client instance certificate store can be controlled by properties in EasyUAClient.SharedParameters.EngineParameters.ApplicationParameters, such as the ApplicationCertificateStore property. By default, OPC Data Client-UA uses a standard directory-based store defined by OPC Foundation ("MachineDefault").

The AllowClientCertificatePrompt property in EasyUAClient.SharedParameters.EngineParameters.ApplicationParameters determines whether the component can interact with the user when checking or creating an application instance certificate. If set to false (the default), no dialogs will be displayed.

Certificate Auto-Creation

If you let OPC Data Client-UA create the certificate and add it to the store, it should be noted that it is a security-sensitive

operation that would typically be allowed only to administrators. OPC Data Client-UA will attempt to do this if the certificate is not found, which may be when the application is first started on the computer, but if your application is not running with privileges required for this operation, the certificate will not be added.

In order to allow your application be run under usual privileges, and make its behavior more predictable, it is recommended that you assure the generation of the certificate during the application deployment, when administrative privileges are usually required anyway. One way to do this is call the static method EasyUAClient.Install during the deployment process. For more information, see the "Application Deployment" chapter.

> ⚠ When using the EasyUAClient.Install method during the deployment process, make sure that the application (certificate) name is the same during deployment, and during the normal application. With automatically generated application name (which is the default), a different name might be generated if you use a separate application for the deployment, or if use you use utilities such as **InstallUtil.exe** which effectively act as a host for your application. In such situations, always set the application name explicitly, to the same value during the deployment and in normal application executions.

Peer Auto-Trust

When OPC Data Client creates or checks the client instance certificate (in the application certificate store), it also makes sure that the certificate is to be found in the trusted peers certificate store. If the client instance certificate store is not found there, a copy of it (without the private key) is placed into the trusted peers certificate store automatically.

With this *peer auto-trust* mechanism, OPC UA servers that use the same trusted peers certificate store can automatically trust the client application(s) created with OPC Data Client.

> ⚠ With the default settings effective when targeting .NET Standard, applications use separate certificate stores and not system-wide "shared" certificate stores. The peer auto-trust mechanism is still invoked under .NET Standard, but with the default settings it may have no observable effect, because other applications are using different certificate stores.

Additional information

OPC-UA requires that both parties (client and server) mutually identify themselves using application certificates. The certificates are supposed to be unique for each application (instance), and therefore cannot be a constant part of the "toolkit" (such as OPC Data Client), and need to be generated. In order to make this process invisible (in common cases) to the developer, OPC Data Client

a) determines the parameters of the certificate automatically, using values such as the EXE name or the calling assembly name,

b) attempts to look up the certificate in the certificate store,

c) if not found, it attempts to create it, and save it into the certificate store.

The algorithm described above does not, however fit well with hosted environments such as IIS, for two reasons:

- It is difficult to automatically determine reasonable and unique parameters for the certificate, because the hosting process is the IIS service, not "your" own application EXE.
- The page processing code in IIS typically runs with low privileges that do not allow it to call the necessary CertificateGenerator utility, and even less to save the new certificate to the store.

For usage in such environments, the recommendation is:

- Pre-generate the application certificate manually, and save it to the certificate store. This will remove the need for the application to create and save the certificate.
- In your application, set your own parameters of the certificate. The application will then use these parameters to look up the certificate.

On Windows, application certificate can be generated using **Opc.Ua.CertificateGenerator.exe** utility, available from the OPC Foundation. The utility is typically located at **"C:\Program Files (x86)\Common Files\OPC Foundation\UA\v1.0\Bin"**. Run it with "/?" to obtain usage instructions.

> OPC Data Client normally does not need the Opc.Ua.CertificateGenerator utility be present on the disk. For COM and .NET Framework target platforms, it has its own internal copy of this utility which it loads and executes. For .NET Standard development platform, the Opc.Ua.CertificateGenerator utility is not used.

Setting the certificate parameters is done by modifying properties in EasyUAClient.SharedParameters.EngineParameters.ApplicationParameters (EasyUAClient.SharedParameteres is a static property, and you need to set the values before creating the first instance EasyUAClient, in order for it to have the desired effect). The properties of interest are:

- ApplicationCertificateSubject
- ApplicationName
- ApplicationUriString
- ProductUriString

The values should match those used when the certificate was generated, because they (or at least some of them) are used to look up the certificate in the store.

The default certificate store for OPC-UA applications is not one of the Windows stores, but instead, a file-system (directory) based store. It defaults to **"%CommonApplicationData%\OPC Foundation\CertificateStores\UA Applications"**, where **%CommonApplicationData%** is e.g. **"C:\ProgramData"**. The best way to inspect the UA certificates (on Windows) is to use the OPC UA Configuration tool from the OPC Foundation. After installation, run (e.g.) Start -> All Programs -> OPC Foundation -> UA SDK 1.01 -> UA Configuration Tool. Then, select the "**Manage Certificates**" tab, press the drop-down next to "**Store Path**", select the store I listed above, and press the View Certificates button.

> OPC Data Client also includes the **UA Configuration Tool** in the Bonus Material part of its full installation for Windows. You can access the **UA Configuration Tool** from the **Start** menu (under OPC Data Client program group), or using the OPC Data Client **Launcher** application.

You should not use the same certificate for multiple applications. And, you should not use the same certificate even for multiple instances of the same application (such as when you deploy the application on multiple computers). Each instance of the application (typically, this means each application/computer combination, but can be even more) should have its own, unique certificate. This is how UA security is meant to work, because there needs to be a way for the server to authenticate each client connection separately and possibly deny the connection to unsecure or compromised clients. Technically, if you violate this and use the same certificate, things will probably work OK on the surface, but it is against the OPC-UA security specs. This is the reason why the certificate is generated anew on the computer - and the cause of some troubles.

Actually, while using the CertificateGenerator manually is possible, it would be probably too complicated to try to assemble the right set of parameters so that the generated certificate is then properly found by the client application. Instead, we suggest that you create a small app (e.g. Windows Forms app, or a console app). In it, you set the 4 parameters in EasyUAClient.SharedParameters to meaningful values, and then call a static method EasyUAClient.Install(). You then run this application with administrator/elevated privileges, and it will create the certificate (verify it with the UA Configuration Tool described above). In your actual client app, set the parameters in precisely the same way before instantiating the EasyUAClient object, and doing so should assure that it will find and use the certificate. Still, your app (which may be a Web app) needs to have read access to the directory of the cert store - you may have to modify the permissions). The additional

app you created may become part of your installation procedure.

Obtaining Instance Certificate from the GDS

If your OPC UA setup includes an OPC UA Global Registration Server (GDS), you might be able to obtain the application instance certificate from the GDS (in the role of Certificate Manager, CM). For more information, see **OPC UA Client Application Service (Section 6.3.1)** (or, less preferrably, **OPC UA Certificate Management Client (Section 6.4.2)**).

Troubleshooting

Some common problem scenarios include:

Certificate generation works on one computer, does not on other. For example, when you first run your application your development computer, you may use the development Web server built-in in Visual Studio. This one uses different accounts and permissions from IIS, and the certificate creates just fine. On the production computer, IIS is used, and the certificate generation may fail. See further below for related information.

Certificate generation fails under IIS. Most likely this is due to permissions. IIS settings are VERY restrictive (for good reason), and the defaults won't allow the certification generation or storing it into the store.

4.13.1.2 Trusting OPC UA Server Instance Certificate

In a secured OPC-UA solution, the OPC server identifies itself to the OPC client using its instance certificate. The OPC client authenticates the certificate and checks whether the communication with that OPC server is authorized. Typically, the process of checking other party's instance certificate is achieved through use of certificate trust lists, accessible programmatically and by means of UA Configuration Tool (installed with our product, and with OPC-UA downloads provided by OPC Foundation).

In This Topic

In OPC Data Client-UA, you can control how server instance certificates are trusted using Certificate Acceptance Policy (UACertificateAcceptancePolicy object) that you can parameterize in the EngineParameters property on the EasyUAClient object.

By default:

- Certificate will be trusted if issued by one of certification authorities found in a "Trusted Issuers" certificate store, while default to a directory-based store at `%CommonApplicationData%\OPC Foundation\CertificateStores\UA Certificate Authorities`.
- Certificate will be trusted if found in a "Trusted Peers" certificate store, which defaults to a directory-based store at `%CommonApplicationData%\OPC Foundation\CertificateStores\UA Applications`.
- Certificate not validated by the above rules will be copied to a "Rejected" certificate store, which defaults to a directory-based store at `%CommonApplicationData%\OPC Foundation\CertificateStores\RejectedCertificates`.
- Connections to some of pre-defined trusted endpoint URL strings are always accepted. The trusted endpoint URL list contains endpoints of OPC Data Client public demo servers. Such connections should not be considered secure!
- If the application is running in user interactive mode, the user is presented with a notification allowing him/her to accept or reject the certificate.

Certificates issued by a certification authority (CA) must contain a verifiable certificate chain leading to the CA. **OPC Data Client requires that the root (CA) certificate must be included in the chain as well.**

As you can see from the rules described above, a certificate that is not initially trusted by the client will be copied to the "Rejected" certificate store. If you know that the server certificate should be trusted, you can locate this rejected certificate and manually move it to the "Trusted Peers" certificate store, which will make it trusted next time it is provided by the server to the client.

Trust Settings

The TrustedEndpointUrlStrings property contains an array of endpoint URLs that are always trusted, without regard for the certificate provided. By default, this list contains endpoint URLs of the demo OPC UA Sample Server on the Internet (opcua.demo-this.com) and the local OPC UA Sample Server, meaning that you will always be able to use the sample servers from OPC Data Client-UA, even if configuration of its instance certificate, or configuration of trusted certificate list for OPC Data Client-UA has done been done properly. In a fully secure configuration, this list should be empty.

The AcceptAnyCertificate property determines whether the client accepts any server certificate, even if a certificate validation error occurs. Setting this property to true effectively bypasses an important security feature in OPC Unified Architecture. Use it only for testing and development purposes, or if your application does not require the server certificate check.

The type and location of trusted issuers certificate store can be controlled by EasyUAClient.SharedParameters.EngineParameters.CertificateAcceptancePolicy.TrustedIssuersCertificateStore property. By default, OPC Data Client-UA uses a standard directory-based store defined by OPC Foundation ("UA Certificate Authorities").

The type and location of trusted peers certificate store can be controlled by EasyUAClient.SharedParameters.EngineParameters.CertificateAcceptancePolicy.TrustedPeersCertificateStore property. By default, OPC Data Client-UA uses a standard directory-based store defined by OPC Foundation ("UA Applications").

The path to the rejected certificate store can be controlled by EasyUAClient.SharedParameters.EngineParameters.CertificateAcceptancePolicy.RejectedCertificateStore property. By default, OPC Data Client-UA uses a standard directory-based store defined by OPC Foundation ("RejectedCertificates").

The AllowUserAcceptCertificate property determines whether the interactive user can be prompted to and accept a server certificate that has failed other validation checks. This setting has effect only when the current process is running in user interactive mode.

Some finer details regarding the server instance checking process can be controlled by a configuration file, if you correspondingly configure the EasyUAClient.SharedParameters.EngineParameters.ConfigurationSources. For more information, see "Application Configuration" chapter under "Advanced Topics".

Refreshing Trust Lists from the GDS

If your OPC UA setup includes an OPC UA Global Registration Server (GDS), you might be able to acquire the trust lists from the GDS (in the role of Certificate Manager, CM) and refresh the certificate stores accordingly. For more information, see **OPC UA Client Application Service (Section 6.3.1)** (or, less preferrably, **OPC UA Certificate Management Client (Section 6.4.2)**).

4.13.1.3 Trusting OPC UA Server HTTPS Certificate

> This article only applies to OPC UA connections made using the HTTPS protocol. You can skip this article if you are not using HTTPS.

An HTTPS connection requires a certificate on (placed on the OPC UA server side) to be used for performing the message encryption. This certificate is different than the application instance certificate of the OPC UA server. The OPC UA client must validate and trust the server's HTTPS certificate for the connection to work.

If you are accustomed to using HTTPS in the Web browser, you may know that the browser uses machine-wide certificate stores to determine whether the HTTPS certificate of the Web server you are connecting to can be trusted. Typically, the HTTPS certificate is issued by a well-known CA (Certification Authority), and certificates of such authorities come with the browser, and are maintained by the operating system (updates) or on an enterprise IT level.

When an HTTPS server certificate is trusted by the machine-wide mechanism, OPC UA client applications created with OPC Data Client will trust it for HTTPS connections to OPC UA servers as well. One option to establish trust for HTTPS server certificates is therefore to use the same mechanism and procedures as for Web browsing. This approach works, but has the disadvantage that it usually requires administrative privileges to manipulate the Internet certificate stores (normally used for Web browsing).

OPC Data Client allows you to use additional rules with server HTTPS certificates. By default, OPC UA client applications created with OPC Data Client will also trust server HTTPS certificates if they are allowed by the rules for server instance certificates, as described in **Trusting OPC UA Server Instance Certificate (Section 4.13.1.2)**. This means that by default:

- Certificate will be trusted if issued by one of certification authorities found in a directory-based store at `%CommonApplicationData%\OPC Foundation\CertificateStores\UA Certificate Authorities`.
- Certificate will be trusted if found in a directory-based store at `%CommonApplicationData%\OPC Foundation\CertificateStores\UA Applications`.
- Certificate not validated by the above rules will be copied to a directory-based store at `%CommonApplicationData%\OPC Foundation\CertificateStores\RejectedCertificates`.
- Connections to some of pre-defined trusted endpoint URL strings are always accepted. The trusted endpoint URL list contains endpoints of OPC Data Client public demo servers. Such connections should not be considered secure!
- If the application is running in user interactive mode, the user is presented with a notification allowing him/her to accept or reject the certificate.

> Certificates issued by a certification authority (CA) must contain a verifiable certificate chain leading to the CA. **OPC Data Client requires that the root (CA) certificate must be included in the chain as well.**

> For HTTPS server certificates, only the scheme (protocol) and authority (host and port) part of the endpoint URL are used for comparisons. This is because on the server side, the certificate is bound to all communications running on a specific port.

In the default state, the HttpsCertificateAcceptancePolicy Property of the UAClientEngineParameters Class contains a null reference. In this state, when you change the policy used for trusting server instance certificates, such changes will also automatically apply to trusting server HTTPS certificates.

You can also specify a different certificate acceptance policy for HTTPS server certificates. To do so, create your own instance of the UACertificateAcceptancePolicy Class, set its properties as needed, and assign it to the HttpsCertificateAcceptancePolicy Property. Note that as with any other static properties of the EasyUAClient Class, this has to be done before any OPC UA operations are invoked.

4.13.1.4 OPC UA Certificate Stores

Certificate Store Types

OPC Data Client can work with certificates located in *certificate stores*. Certificate stores are of different types; they are either:

- **platform-specific** certificate store (Windows, Linux, ...), or
- **directory** in a file system.

For more details on each of these types, see **OPC UA Platform-specific Certificate Stores (Section 4.13.1.4.2)** and **OPC UA Directory Certificate Stores (Section 4.13.1.4.1)**.

In This Topic

Certificate Store Path

The certificate store is identified by a string, called *certificate store path*. The syntax and semantics of this string is as follows:

- If the string starts with **"LocalMachine\"** (case insensitive), it denotes a platform-specific certificate store for the local computer. The store name follows this prefix.
- If the string starts with **"CurrentUser\"** (case insensitive), it denotes a platform-specific certificate store for the current user. The store name follows this prefix.
- Otherwise, the string denotes a certificate store located in a file system directory, and the value is equal to the directory path. The string can contain replaceable *tokens* that refer to specific locations. For details, see **OPC UA Directory Certificate Stores (Section 4.13.1.4.1)**.

Certificate Store Locations

OPC Data Client uses several certificate stores for its operations. The location of the stores is given by various parameters. The stores are:

- **Application certificate store**. A client application created with OPC Data Client looks for or creates its own instance certificate here. The location of the store is controlled by EasyUAClient.SharedParameters.EngineParameters.ApplicationParameters.ApplicationCertificateStore property. For more details, see **Providing OPC UA Client Instance Certificate (Section 4.13.1.1)**. The application instance certificates in this store include the private keys.
- **Rejected certificate store**. Server certificates that fail validation are placed into this store. Normally the certificates in this store do not include the private key, but in some cases they may (when the validation of application's own instance certificate fails - as opposed to validation of certificate belonging to the other communication party).
- **Trusted issuers certificate store**. Contains certificates of Certification Authorities to be trusted.
- **Trusted peers certificate store**. Contains specific OPC UA application instance certificates to be trusted.

For details on rejected certificate store, trusted issuers certificate store and trusted peers certificate store, see **Trusting OPC UA Server Instance Certificate (Section 4.13.1.2)** and **Trusting OPC UA Server HTTPS Certificate (Section 4.13.1.3)**.

Default Settings

When targeting .NET Framework, all certificates that OPC Data Client works with are located in some "shared" directory-

based certificate store by default. Specifically:

- Default application certificate store is **"%CommonApplicationData%\OPC Foundation\CertificateStores\MachineDefault"**.
- Default rejected certificate store is **"%CommonApplicationData%\OPC Foundation\CertificateStores\RejectedCertificates"**.
- Default trusted issuers certificate store is **"%CommonApplicationData%\OPC Foundation\CertificateStores\UA Certificate Authorities"**.
- Default trusted peers certificate store is **"%CommonApplicationData%\OPC Foundation\CertificateStores\UA Applications"**.

On Windows, the **%CommonApplicationData%** token typically resolves to something like **"C:\ProgramData"** (note that this folder is hidden by default). See **OPC UA Directory Certificate Stores (Section 4.13.1.4.1)** for more details.

When targeting .NET Standard, all certificates that OPC Data Client works with are located in a directory-based certificate store under the current working directory by default. Specifically:

- Default application certificate store is **"%LocalFolder%/OPC Foundation/CertificateStores/MachineDefault"**.
- Default rejected certificate store is **"%LocalFolder%/OPC Foundation/CertificateStores/RejectedCertificates"**.
- Default trusted issuers certificate store is **"%LocalFolder%/OPC Foundation/CertificateStores/UA Certificate Authorities"**.
- Default trusted peers certificate store is **"%LocalFolder%/OPC Foundation/CertificateStores/UA Applications"**.

See **OPC UA Directory Certificate Stores (Section 4.13.1.4.1)** for explanation of the **"%LocalFolder"%** token, and more details.

> Other commonly used setting for application certificate store location under .NET Standard is **"CurrentUser\UA_MachineDefault"**.

Certificate Store Security

In a secure deployment, the certificate store itself (that is, read and write access to the certificates it contains) must be secured. OPC Data Client needs appropriate permissions to read from (and sometimes write to) the certificate stores. At the same time, access should be denied to unauthorized actors. This is most critical for the write access to the stores (and for read access to the private key parts). Securing the certificate stores is outside of OPC Data Client scope.

> OPC Data Client does not use passwords to access certificate private keys, and the certificates it creates are not protected by passwords. Be aware that the private keys in OPC UA certificate stores for OPC Data Client usage are not protected by passwords.

4.13.1.4.1 OPC UA Directory Certificate Stores

Structure of the Directory Certificate Store

In This Topic

As described in **OPC UA Certificate Stores (Section 4.13.1.4)**, *directory certificate stores* reside in a file system. In many cases, their structure can remain an opaque implementation detail to you. Knowing the structure comes handy if you need to deal with them externally or manually.

There are no files at the "root" of the directory certificate, only sub-directories, and they are:

- The **"certs"** subdirectory. Contains the certificates without private keys, in .DER format.
- The **"crl"** subdirectory (only in certificate stores which need it). Contains the certificate revocation lists (CRLs) for the certificate store.
- The **"private"** subdirectory (only in certificate stores which need it). Contains the certificate *with* private keys, in .PFX format. Instead of .PFX, it can also contain just the private key, in .PEM format (OPC Data Client recognizes this but does not itself create files in directory certificate stores in this way).

If the certificate store contains a certificate with a private key, it will therefore be present in both **"certs"** and **"private"** subdirectories, each time in a different format.

The file name of each certificate comprises of the certificate common name (from its subject), followed by a space, and the certificate thumbprint in square brackets, e.g. **"My Application [71511464F08D30AF9F9B2BC21CDB78D49BE568B8]"**. Special characters (like **< > : " / \ | ? ***) that cannot appear in file names are stripped off from the common name.

> OPC Foundation has a **UA Configuration Tool** which can be used to manage the certificates related to OPC UA on Windows machines (both in the directory certificate stores, and in Windows certificate stores). OPC Data Client includes this tool in the Bonus Material part of its full installation for Windows. You can access the **UA Configuration Tool** from the **Start** menu (under OPC Data Client program group), or using the OPC Data Client **Launcher** application.

Syntax of Directory Certificate Store Path

In its simplest form, the directory certificate store path is an absolute path to the directory that holds the store, e.g. **"C:\ProgramData\OPC Foundation\CertificateStores\MachineDefault"**. Since absolute paths are not flexible enough and may fail to work when the application is transferred to a computer with different configuration, OPC Data Client allows you to include replaceable *tokens* in the directory certificate store path. A token is enclosed in percentage sign characters, e.g. **%CommonApplicationData%**. For the token to be recognized, the directory certificate store path must begin directly with the token (the percent sign). Tokens are not recognized further down in the string.

The following two types of tokens can be used. OPC Data Client searches for them from top to bottom.

- **Special folders**. Any enumerated constant name from the .NET Environment.SpecialFolder enumeration (https://docs.microsoft.com/en-us/dotnet/api/system.environment.specialfolder) can be used as a token. The token is replaced by the absolute path of the corresponding special folder. Not all available special folders make sense with OPC UA, but the following ones are good candidates: CommonApplicationData, CommonProgramFiles, ProgramFiles, etc.
- **Environment variables**. These are the operating system environment variable names, as available to the current process. The value of the environment variable is retrieved, and replaces the token.
- On .NET Standard development platform only: "**%LocalFolder%**" (case sensitive). The current working directory of the application replaces the token. The string does not end with a backslash (\) or a slash (/).

If the token name is not recognized, the token is replaced by an empty string (i.e. the token is removed).

Platform Differences

The default certificate store paths have very different defaults in .NET Framework and .NET Standard.

In .NET Framework, the default certificate stores paths are "shared"; that is, by default, all applications developed with OPC Data Client share the same certificate stores, which are system-wide.

In .NET Standard, the default certificate stores paths are all in directories that are located under the current working directory of the application.

In .NET Framework

When you target .NET Framework with OPC Data Client, the default directory certificate store paths all start with the **%CommonApplicationData%** token, which on Windows typically resolves to something like **"C:\ProgramData"** (this is independent of whether your development target is .NET Framework or .NET Standard). Note: On Linux, the **%CommonApplicationData%** token typically resolves to **"/usr/share"**, but that would only be of interest in .NET Standard (see below), if you change the default store paths values.

> ⚠ In a default Windows installation, the "**C:\ProgramData**" directory exists, but it is hidden. You need to use appropriate setting or tool in order to be able to inspect the contents of hidden directories.

Example: The default application certificate store path is specified as **"%CommonApplicationData%\OPC Foundation\CertificateStores\MachineDefault"**, and on Windows, it may resolve to **"C:\ProgramData\OPC Foundation\CertificateStores\MachineDefault"** (note that the "C:\ProgramData" folder is hidden).

In .NET Standard

When you target .NET Standard with OPC Data Client, the default directory certificate store paths all start with the **%LocalFolder%** token, which on resolves to the current working directory of the application.

Example: The default application certificate store path is specified as **"%LocalFolder%/OPC Foundation/CertificateStores/MachineDefault"**. You will therefore have an **"OPC Foundation"** sub-directory in your current working directory, and a structrie of the certificate stores below it.

> ⚠ Make sure you secure the directory certificate stores properly. This caution is particularly relevant with the default .NET Standard settings, because you may end up with multiple certificate stores (directories) to be secured, not just the common "shared" one. Also note that the absence of the "shared" and commonly used certificate stores prevents certain inter-application cooperation scenarios from working, such as the practice that the OPC UA application stores its own application certificate to the trusted peers certificate store on the same machine, to make it easier for local connections to be established "out of the box".

4.13.1.4.2 OPC UA Platform-specific Certificate Stores

The *platform-specific certificate stores* are implemented and maintained by the operating system or the runtime. As explained in **OPC UA Certificate Stores (Section 4.13.1.4)**, you specify the platform-specific certificate store by starting the certificate store path by either **"LocalMachine\"** or **"CurrentUser\"**.

- If the string starts with **"LocalMachine\"** (case insensitive), it denotes a platform-specific certificate store for the local computer. Commonly used examples are: **"LocalMachine\My"**,

In This Topic

"LocalMachine\UA Applications" or "**LocalMachine\UA Certificate Authorities**".

- If the string starts with **"CurrentUser\"** (case insensitive), it denotes a platform-specific certificate store for the current user. Commonly used examples are: **"CurrentUser\My"** or **"CurrentUser\Root"**.

The store name follows the prefix.

> ⚠ Some older code or documentation might use the term "Windows certificate store" for certificate stores that can, in fact, now be implemented also on other platforms, such as Linux. This is due to the Windows origins of such code or documentation. As OPC Data Client now supports multiple development platforms and operating systems, in new documents we consistently use the term "platform-specific certificate store" wherever we refer to a general platform-provided certificate store concept. In new documents, we use the term "Windows certificate store" only to refer to a specific implementation of platform-specific certificate store on Windows operating system. Similarly, we would use "Linux certificate store" to refer to a platform-specific certificate store in a way that is implemented in Linux (which may differ by the particular .NET runtime, e.g. .NET Core).

C#

```
// This example demonstrates how to place the client certificate in the platform-specific (Windows,
Linux, ...) certificate
// store.

using System;
using OpcLabs.EasyOpc.UA;

```

Windows Certificate Stores

Windows has a support for certificate stores built into the operating system, and corresponding APIs and tools to access the certificate stores. On Windows, OPC Data Client simply uses the mechanisms provided by Windows to support platform-specific certificate stores. For more information about Windows certificate stores, see e.g. Managing Certificates with Certificate Stores and How to Use the Certificates Console.

To manage the local computer certificates on Windows, type ***certlm.msc*** into the Windows search box, and press ***Enter***. You will need administrative privileges to manage the local computer certificates.

To manage the certificates for the current user on Windows, type ***certmgr.msc*** into the Windows search box, and press ***Enter***.

Note, however, that the logical store names displayed by the management console are not the same as the physical certificate store names, and that some stores may not be displayed at all.

OPC Foundation has a **UA Configuration Tool** which can be used to manage the certificates related to OPC UA on Windows machines (both in the directory certificate stores, and in Windows certificate stores). OPC Data Client includes this tool in the Bonus Material part of its full installation for Windows. You can access the **UA Configuration Tool** from the **Start** menu (under OPC Data Client program group), or using the OPC Data Client **Launcher** application.

Linux Certificate Stores

On Linux under .NET Core, the platform-specific certificate stores are implemented as follow:

- The certificates for the local computer are stored according to the rules valid on the particular Linux distro.
- The certificates for the current user are stored using an internal .NET Core mechanism (which currently appears to be a dedicated directory under ~/.dotnet, but that is considered an implementation details that may change in future versions).

For more information, see e.g. Provide a way for sysadmins to manage the .Net Core "My" certificate store on non-Windows platforms .

4.13.1.5 Security in OPC UA Endpoint Selection

As explained earlier, a single OPC-UA server may have multiple endpoints with the same functionality, but using different protocols, or different security settings (for example, an endpoint that provide message security may exist alongside with endpoint that does not provide message security). When OPC Data Client is given an endpoint URL, it does not yet (in general case) precisely determine the actual OPC UA server endpoint that the client wil lbe connecting to.

In order to influence which endpoint will get used, you can configure an OPC UA Endpoint Selection Policy. The policy can specifies various aspects of the endpoint you wish to connect to. Some of them are not related to security (for example, data encoding). Many aspects of the endpoint selection policy have, however, direct effect on the resulting security of the communication between the OPC UA client and the OPC UA server.

See **OPC UA Server Endpoints (Section 4.11.1)** for information about how to set the endpoint selection policy either globally, or just for a single endpoint descriptor. See **OPC UA Endpoint Selection Policy (Section 4.11.1.1)** for information about the contents of the policy, and meaning of its various parameters.

5 Development Models

OPC Data Client offers several development models. Each development model is a kind of approach to solving the problem. Some development models involve imperative programming (traditional coding), while others do not require programming in the usual sense, or the programming approach is dubstantially different. The various development models are described in the chapters further below.

The following table shows which development models are available for different development platforms:

	COM	**.NET Framework**	**.NET Standard**	**Excel** (with **Excel Option (Section 12.1)**)
Imperative Programming Model	✓	✓	✓	× (1)
Live Binding Model (Windows Forms, WPF)	×	✓	×	×
Live Mapping Model	×	✓	✓	×
Reactive Programming Model	×	✓	✓	×
Real-time Data Spreadsheet	×	×	×	✓

Notes: (1) This functionality is not directly available on the development platform, but can be achieved by combining with VBA code (through COM platform).

Multiple different development models can be freely mixed in the same project.

In OPC Data Client-COM, only the imperative programming model is available.

The User Interface object belong logically under the Imperative Programming Model, although they are described separately, because they are simply an extension for a specific purpose, and not all developers need to use them.

5.1 Imperative Programming Model

In the imperative programming development model, you write code that calls methods on OPC Data Client objects. You prepare and pass in the arguments necessary, and get back the results that you can process further.

This is the traditional model, “natural” to software developers. Its advantage is that you have high level of control over what is happening, and you can structure the code the way you like it. The disadvantage is that you may end up writing more code than it is necessary, compared to other models.

5.1.1 Operational Methods Overview

"Operational methods" are methods that communicate with the target environment (OPC servers etc.), directly or indirectly. Auxiliary methods, which may also exist on the objects, are not listed here.

Many methods exist in two forms:

- Single-operation.
- Multiple-operations.

In OPC, operations are much more effective if performed together in a group, at once. For example, doing a read of 100 values is much faster if performed at once, using the multiple-operation method, instead of repeatedly calling the single-operation method in a loop. For this reason, you should use the multiple-operation methods whenever possible. An exception to this rule are methods that act as substitute for event handlers (these methods are consistently named **Pull*XXXX***), where the recommendation is the opposite - you should normally use the single-operation method form instead.

In This Topic

Operational method naming conventions

The name of the operational method usually consists of a verb that denotes what the method does, and sometimes a noun which describes either the affected entity (such as in "ReadItem", or the outcome of the method (such as in "BrowseObjects").

Usually, the name of the multi-operation method is derived from the name of the single-operation method by using a plural instead of singular form of the noun (if it is present), and preceding the noun it with "Multiple" (or adding it at the end, when the noun is missing). For example, "ReadItem" becomes "ReadMultipleItems", and "Write" becomes "WriteMultiple". Such methods use an array of argument objects (one for each operation) as an input, and return an array of results (one for each operation again); the indexes in the output array correspond to the indexes in the input array.

When an input or output array is replaced by a list in the method signature, a word "List" appears at the end of the method name. This happens with all multiple-operation methods (where the word "Multiple" is removed then), and also with some single-operation methods where the argument or result happens to an array already.

> ⚠ Conceptually, the methods with "List" in their name are performing the same operations as those without it. Except where it is specifically needed, this documentation therefore does not refer to these methods explicitly. The name of the base method is used instead. For example, when this document talks about the "ReadMultipleValue" method, the method "ReadValueList" is also implied.

Legend to the tables

This chapter explains some of the notation used in the tables that follow:

- **bold**
- *italics*
- grayed out

When two or more methods appear in the table cell on the same line, separated by a comma, they perform precisely the same function, but differ only in the form of arguments accepted or results returned. Typically, this is with method that work with lists, that ar in addition to methods that work with arrays.

When multiple lines with different methods are listed inside a single table cell, then other methods with slightly different purpose are all derived (by extension) from the primary method listed in **bold**. This grouping helps you to understand the internal relations of the methods, where only a handful of primary methods is used to provide richer functionality, by means of method overloads, or methods with different names. The primary method is always the most general one and can always be used. It is, however, often more convenient to use the derived methods, which are more specialized, and give shorter and more understandable code.

Methods listed in the tables here are considered (unless stated otherwise), for the purpose of the explanation in this document to be methods of the objects listed even though (in .NET) in reality, they may be implemented as extension methods on the object or interface. They are also generally available under COM development platform, on the respective COM interfaces. There are other sets of extension methods, for .NET only, which further enhance the functionality of listed objects. These extension methods are not listed here, but rather under **Layered Extensions for .NET (Section 7.1)**.

Methods that are only available on the COM development platform are listed in *italics*. They are currently methods that accept or return lists instead of arrays, which is a necessity for some COM tools or languages that lack a sufficient support for COM safe arrays.

Methods that primarily exist for internal implementation (infrastructure) reasons are grayed out, and you should not normally used them.

EasyDAClient operation methods

This object is for OPC Data Access (OPC "Classic", COM/DCOM-based) and for OPC XML-DA.

Purpose	Single-operation Method	Multiple-operations Method
Read a named item (value/timestamp/quality).	ReadItem	**ReadMultipleItems**, *ReadItemList*
Read a named item value.	ReadItemValue	**ReadMultipleItemValues**, *ReadItemValueList*
Get value of OPC property.	GetPropertyValue	**GetMultiplePropertyValues**, *GetPropertyValueList*
Write a named item (value/timestamp/quality).	WriteItem	**WriteMultipleItems**, *WriteItemList*
Write value into a named item.	WriteItemValue	**WriteMultipleItemValues**, *WriteItemValueList*
Browse the computer for OPC (DA) servers.	**BrowseServers**	
Browse for child nodes. Browse for child branches. Browse for child leaves.	**BrowseNodes** BrowseBranches BrowseLeaves	
Browse for access paths.	**BrowseAccessPaths**, *BrowseAccessPathList*	
Browse for available item properties.	**BrowseProperties**	
Subscribe to changes of an OPC item.	SubscribeItem	**SubscribeMultipleItems**, *SubscribeItemList*

Change parameters of a subscription to an OPC item.	ChangeItemSubscription	**ChangeMultipleItemSubscriptions**, *ChangeItemSubscriptionList*
Unsubscribe from changes of an OPC item.	UnsubscribeItem	**UnsubscribeMultipleItems**, *UnsubscribeItemList*
Unsubscribe from changes of all OPC items.	**UnsubscribeAllItems**	
Attempt to pull an OPC item change.	**PullItemChanged**	**PullMultipleItemChanges**, *PullItemChangeList*

EasyAEClient operation methods

This objects is for OPC Alarms and Events (OPC "Classic", COM/DCOM-based).

Purpose	Single-operation Method	Multiple-operations Method
Get the current state information for a condition instance.	**GetConditionState**, *GetConditionStateList*	
Acknowledge a condition in the event server.	**AcknowledgeCondition**	
Browse the computer for OPC (A&E) servers.	**BrowseServers**	
Browse for child nodes. Browse for event areas. Browse for event sources.	**BrowseNodes** BrowseAreas BrowseSources	
Find event categories supported by the server. Find event conditions supported by an event category. Find attributes associated with an event category.	**QueryEventCategories** QueryCategoryConditions QueryCategoryAttributes	
Find event conditions associated with the source.	**QuerySourceConditions**	
Subscribe to OPC events.	**SubscribeEvents**	
Change parameters of an event subscription.	**ChangeEventSubscription**	
Force a refresh of active and inactive unacknowledged conditions.	**RefreshEventSubscription**	
Unsubscribe from particular OPC events.	**UnsubscribeEvents**	
Unsubscribe from changes of all OPC events.	**UnsubscribeAllEvents**	
Attempt to pull an OPC event.	**PullNotification**	PullMultipleNotifications, PullNotificationList

EasyUAClient operation methods

This object is for OPC Unified Architecture (OPC UA).

Purpose	Single-operation Method	Multiple-operations Method
Browse nodes in server's address space. Browse data nodes. Browse data variables. Browse event sources. Browse OPC methods. Browse notifiers. Browse OPC objects. Browse OPC object types. Browse OPC properties. Browse OPC variables.	Browse BrowseDataNodes BrowseDataVariables BrowseEventSources BrowseMethods BrowseNotifiers BrowseObjects BrowseObjectTypes BrowseProperties BrowseVariables	**BrowseMultiple**, *BrowseList*
Call OPC method.	CallMethod	**CallMultipleMethods**, *CallMethodList*
Change parameters of a subscription. Change parameters of a data change subscription.	ChangeMonitoredItemSubscription ChangeDataChangeSubscription	**ChangeMultipleMonitoredItemSubscriptions**, *ChangeMonitoredItemSubscriptionList* ChangeMultipleDataChangeSubscriptions
Discover OPC elements using a generalized query. Discover available OPC applications (LDS). Discover available endpoints of a server (LDS). Discover available OPC servers on a host (LDS). Discover available OPC servers on a network (LDS-ME). Find OPC applications, given LDS endpoints. Globally discovers OPC applications (GDS). Globally discovers OPC servers (GDS).	**Discover** DiscoverLocalApplications DiscoverLocalEndpoints DiscoverLocalServers DiscoverNetworkServers FindLocalApplications DiscoverGlobalApplications DiscoverGlobalServers	
Attempt to pull OPC data change notification.	**PullDataChangeNotification**	**PullMultipleDataChangeNotifications**, *PullDataChangeNotificationList*

Attempt to pull OPC event notification.	**PullEventNotification**	**PullMultipleEventNotifications**, *PullEventNotificationList*
Attempt to pull OPC server condition change notification.	**PullServerConditionChange**	**PullMultipleServerConditionChanges**, *PullServerConditionChangeList*
Read data of a given node's attribute. Read value of a given node's attribute.	Read ReadValue	**ReadMultiple**, *ReadList* ReadMultipleValues, *ReadValueList*
Subscribe to changes of a monitored item. Subscribe to data changes. Subscribe to events.	SubscribeMonitoredItem SubscribeDataChange SubscribeEvent	**SubscribeMultipleMonitoredItems**, *SubscribeMonitoredItemList*
Unsubscribe from changes of a monitored item.	UnsubscribeMonitoredItem	**UnsubscribeMultipleMonitoredItems**, *UnsubscribeMonitoredItemList*
Unsubscribe from changes of all monitored items.	**UnsubscribeAllMonitoredItems**	
Write data into a node. Write value into a node.	Write WriteValue	**WriteMultiple**, *WriteList* WriteMultipleValues, *WriteValueList*

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

5.1.1.1 Multiple-operation Methods

As described in **Operational Methods Overview (Section 5.1.1)**, OPC operations are much more effective if performed together - multiple operations at once. Multiple-operation methods allow you to perform such simultaneous operations, and you should use whenever possible, over single-operation methods.

By convention, multiple-operation methods always contain the word "Multiple" in their name.

In This Topic

Arguments and return values as arrays

In its basic form, the multiple-operation method takes an array (of multiple arrays) of arguments as an input, and produces (as an output) a return value which is an array of results.

The size of the output array is the same as the size of the input array(s), and an element at each index in the result array contains a result that corresponds to the arguments at the same index in the input array(s).

Arguments and return values as lists

This functionality is not available under (or the text does not apply to) .NET development platform (.NET Framework, .NET Standard).

Some COM tools and languages (e.g. PowerScript in PowerBuilder) lack the ability to properly provide or process arrays of COM objects. In such case, using multiple-operation methods would be impossible using their standard array-based form.

In order to make the use of multiple-operations methods in such tools and language possible, OPC Data Client introduces an alternative form of these methods, where arrays are replaced by lists (objects). You can then use methods and properties on the list object in order to access its element, instead of indexing an array. By convention, the list-based methods always contain the word "List" in their name. For correspondence between the array-based and list-based methods, see **Operational Methods Overview (Section 5.1.1)**. Of course, if you prefer, you can use the list-based methods from other tools and languages as well.

The order of elements in the return value corresponds with the order of elements in the method arguments. List elements can also be accessed by index, and therefore an element of the returned list corresponds at certain index corresponds to the element of the arguments list at the same index.

There are also single-operation methods that accepts list instead of array, in case that the argument or return value is an array already, even for a single-operation method. In such case, most of the discussion in this topic can also be applied, except for the correspondence of the order and/or indexes between the arguments and the return value.

Creating and accessing the list

A list object that is passed to a list-based multiple-operation method can be any object that implement the IList Interface. A list object returned from the method also derived from the same interface; in fact, it may provide even broader guarantees as to what interfaces are supported.

You will typically use following members of the list object in order to meaningfully create the list and acess its elements:

- Count Property. Gets the number of elements contained in the list.
- Item[Int32] Property. Gets or sets the element at the specified index.
- Add Method. Adds an item to the list.

In principle, a list can also be enumerated using standard COM collection enumeration approach, although various COM tools and languages also fail implementing it properly. You can, however, use a standard "for" loop, available in practically all languages, with an integer counter, and access the list's element by index. List indexes are zero-based, i.e. the range of valid indexes (for already existing elements of the list) is between 0 and (Count - 1).

The ElasticVector object

OPC Data Client provides an ElasticVector Class, which you can conveniently use to provide list-based arguments to multiple-operation methods. The ElasticVector implements the IList Interface, and has a handful of additional useful members as well.

Above that, it is truly "elastic", in the sense that it can grow automatically with certain operations. It does not shrink by itself. The growing constitutes of lowering the lower bound or increasing the upper bound as necessary for the operation. The absolute element indexes remain unchanged, even when the lower bound changes.

Setting an element at specified index is, for example, always a valid operation with the ElasticVector, regardless of whether the index falls between the current lower and upper bounds of the vector. If it falls outside the range, the bounds are automatically adjusted as needed. This allows the object be used without having to explicitly set the vector dimensions first.

Following examples shows usage of the ElasticVector Class for passing a list of arguments into a multiple-operation method. The example also shows how the return value from the multiple-operation method, which is a list again, can be processed and its elements extracted.

PowerScript

```
// This example shows how to read the Value attributes of 3 different nodes at once. Using the same
method, it is also possible
// to read multiple attributes of the same node.

mle_outputtext.Text = ""

// Instantiate the client object
OLEObject client
```

```
client = CREATE OLEObject
client.ConnectToNewObject("OpcLabs.EasyOpc.UA.EasyUAClient")

// Prepare arguments. By default, the Value attributes of the nodes will be read.

OLEObject readArguments1
readArguments1 = CREATE OLEObject
readArguments1.ConnectToNewObject("OpcLabs.EasyOpc.UA.OperationModel.UAReadArguments")
readArguments1.EndpointDescriptor.UrlString = "http://opcua.demo-this.com:51211/UA/SampleServer"
readArguments1.NodeDescriptor.NodeId.ExpandedText = "nsu=http://test.org/UA/Data/;i=10845"

OLEObject readArguments2
readArguments2 = CREATE OLEObject
readArguments2.ConnectToNewObject("OpcLabs.EasyOpc.UA.OperationModel.UAReadArguments")
readArguments2.EndpointDescriptor.UrlString = "http://opcua.demo-this.com:51211/UA/SampleServer"
readArguments2.NodeDescriptor.NodeId.ExpandedText = "nsu=http://test.org/UA/Data/;i=10853"

OLEObject readArguments3
readArguments3 = CREATE OLEObject
readArguments3.ConnectToNewObject("OpcLabs.EasyOpc.UA.OperationModel.UAReadArguments")
readArguments3.EndpointDescriptor.UrlString = "http://opcua.demo-this.com:51211/UA/SampleServer"
readArguments3.NodeDescriptor.NodeId.ExpandedText = "nsu=http://test.org/UA/Data/;i=10855"

OLEObject readArgumentsList
readArgumentsList = CREATE OLEObject
readArgumentsList.ConnectToNewObject("OpcLabs.BaseLib.Collections.ElasticVector")
readArgumentsList.Add(readArguments1)
readArgumentsList.Add(readArguments2)
readArgumentsList.Add(readArguments3)

// Obtain values.
OLEObject valueResultList
valueResultList = client.ReadValueList(readArgumentsList)

// Display results
Int i
FOR i = 0 TO valueResultList.Count - 1
    OLEObject valueResult
    valueResult = valueResultList.Item[i]
    IF valueResult.Succeeded THEN
        mle_outputtext.Text = mle_outputtext.Text + "Value: " + String(valueResult.Value) + "~r~n"
    ELSE
        mle_outputtext.Text = mle_outputtext.Text + "*** Failure: " + valueResult.ErrorMessageBrief
+ "~r~n"
    END IF
NEXT

// Example output:
//
//Value: 8
//Value: -8.06803E+21
//Value: Strawberry Pig Banana Snake Mango Purple Grape Monkey Purple? Blueberry Lemon^
```

5.1.2 Imperative Programming Model for OPC Data (Classic and UA)

Data Access deals with the representation and use of automation data in OPC Servers. This chapter gives you guidance in

how to implement the common tasks that are needed when dealing with OPC Data Access server from the client side. You achieve these tasks by calling methods on the EasyDAClient or the EasyUAClient object.

5.1.2.1 Obtaining Information (OPC Data)

Methods described in this chapter allow your application to obtain information from the underlying data source that the OPC server connect to (reading OPC Classic items, or value attributes of OPC UA nodes), or from the OPC server itself (getting OPC Classic property values). It is assumed that your application already somehow knows how to identify the data it is interested in. If the location of the data is not known upfront, use methods described in Browsing for Information chapter first.

5.1.2.1.1 Reading from OPC Classic Items

In OPC Data Access, reading data from OPC items is one of the most common tasks. The OPC server generally provides current data for any OPC item in form of a Value, Timestamp and Quality combination (VTQ).

In This Topic

A single item

If you want to read the current VTQ from a specific OPC item, call the ReadItem method. You pass in individual arguments for machine name, server class, ItemID, and an optional data type. You will receive back a DAVtq object holding the current value, timestamp, and quality of the OPC item. The ReadItem method returns the current VTQ, regardless of the quality. You may receive an **Uncertain** or even **Bad** quality (and no usable data value), and your code needs to deal with such situations accordingly.

C#

```
// This example shows how to read a single item, and display its value, timestamp and quality.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class ReadItem
    {
        public static void Main1()
        {
            var client = new EasyDAClient();

            DAVtq vtq;
            try
            {
                vtq = client.ReadItem("", "OPCLabs.KitServer.2", "Simulation.Random");
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message);
                return;
            }

            Console.WriteLine("Vtq: {0}", vtq);
        }
    }
}
```

PHP

```
// This example shows how to read a single item, and display its value, timestamp and quality.

$Client = new COM("OpcLabs.EasyOpc.DataAccess.EasyDAClient");

try
{
    $Vtq = $Client->ReadItem("", "OPCLabs.KitServer.2", "Simulation.Random");
}
catch (com_exception $e)
{
    printf("*** Failure: %s\n", $e->getMessage());
    Exit();
}

printf("Vtq: %s\n", $Vtq);
```

VB.NET

```
' This example shows how to read a single item, and display its value, timestamp and quality.

Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess._EasyDAClient
    Partial Friend Class ReadItem
        Public Shared Sub Main1()
            Dim client = New EasyDAClient()

            Dim vtq As DAVtq
            Try
                vtq = client.ReadItem("", "OPCLabs.KitServer.2", "Simulation.Random")
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message)
                Exit Sub
            End Try

            Console.WriteLine("Vtq: {0}", vtq)
        End Sub
    End Class
End Namespace
```

JScript

```
// This example shows how to read a single item, and display its value, timestamp and quality.

var Client = new ActiveXObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient");
var VTQ = Client.ReadItem("", "OPCLabs.KitServer.2", "Simulation.Random");
WScript.Echo("VTQ.ToString(): " + VTQ.ToString());
```

Object Pascal

```
// This example shows how to read a single item, and display its value, timestamp and quality.

class procedure ReadItem.Main;
var
  Client: OpcLabs_EasyOpcClassic_TLB._EasyDAClient;
  Vtq: _DAVtq;
begin
  // Instantiate the client object
  Client := CoEasyDAClient.Create;

  try
```

```
    Vtq := Client.ReadItem('', 'OPCLabs.KitServer.2', 'Simulation.Random');
  except
    on E: EOleException do
    begin
      WriteLn(Format('*** Failure: %s', [E.GetBaseException.Message]));
      Exit;
    end;
  end;

  // Display results
  WriteLn('Vtq: ', Vtq.ToString);
end;
```

PowerScript

```
// This example shows how to read a single item, and display its value, timestamp and quality.

mle_outputtext.Text = ""

// Instantiate the client object
OLEObject client
client = CREATE OLEObject
client.ConnectToNewObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")

// Obtain value/timestamp/quality
OLEObject vtq
TRY
    vtq = client.ReadItem("", "OPCLabs.KitServer.2", "Demo.Ramp")
CATCH (OLERuntimeError oleRuntimeError)
    mle_outputtext.Text = mle_outputtext.Text + "*** Failure: " + oleRuntimeError.Description +
"~r~n"
    RETURN
END TRY

// Display results
mle_outputtext.Text = mle_outputtext.Text + "Vtq: " + vtq.DisplayString + "~r~n"
```

VBScript

```
Rem This example shows how to read a single item, and display its value, timestamp and quality.

Option Explicit

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
On Error Resume Next
Dim Vtq: Set Vtq = Client.ReadItem("", "OPCLabs.KitServer.2", "Simulation.Random")
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0
WScript.Echo "Vtq: " & Vtq
```

In OPC Data Client.NET, you can also pass ServerDescriptor and DAItemDescriptor objects in place of individual arguments to the ReadItem method.

C#

```
// This example shows how to read a single item using a browse path, and display its value,
timestamp and quality.

using System;
using OpcLabs.EasyOpc;
using OpcLabs.EasyOpc.DataAccess;
```

```
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class ReadItem
    {
        public static void BrowsePath()
        {
            var client = new EasyDAClient();

            DAVtq vtq;
            try
            {
                vtq = client.ReadItem(
                    new ServerDescriptor("", "OPCLabs.KitServer.2"),
                    new DAItemDescriptor(null, "/Simulation/Random"));
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message);
                return;
            }

            Console.WriteLine("Vtq: {0}", vtq);
        }
    }
}
```

VB.NET

```
' This example shows how to read a single item using a browse path, and display its value, timestamp
and quality.

Imports OpcLabs.EasyOpc
Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess._EasyDAClient
    Partial Friend Class ReadItem
        Public Shared Sub BrowsePath()
            Dim client = New EasyDAClient()

            Dim vtq As DAVtq
            Try
                vtq = client.ReadItem(New ServerDescriptor("", "OPCLabs.KitServer.2"), New
DAItemDescriptor(Nothing, "/Simulation/Random"))
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message)
                Exit Sub
            End Try

            Console.WriteLine("Vtq: {0}", vtq)
        End Sub
    End Class
End Namespace
```

Multiple items

For reading VTQs of multiple items simultaneously in an efficient manner, call the ReadMultipleItems method (instead of multiple ReadItem calls in a loop). You will receive back an array of DAVtqResult objects.

In OPC Data Client.NET, you can pass in a ServerDescriptor object and an array of DAItemDescriptor objects, or an array of DAItemArguments objects, to the ReadMultipleItems method.

C#

```
// This example shows how to read 4 items at once, and display their values, timestamps and
qualities.

using System;
using System.Diagnostics;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class ReadMultipleItems
    {

Read parameters

Note: In OPC Data Client.NET, you can use the optional argument of type DAReadParameters, and then set the ValueAge property in it to control how "old" may be the values you receive by reading from OPC items. With the DataSource property, you can also specify that you want values from the device, or from cache. You can also use the pre-defined DAReadParameters.CacheSource and DAReadParameters.DeviceSource constants to specify the read parameters. There are also overloads of ReadXXXX methods that accept an integer valueAge argument.

Be aware that it is physically impossible for any system to always obtain fully up-to-date values all the time.

VBScript

```
Rem This example shows how to read 4 items from the device, and display their values, timestamps and
qualities.

Option Explicit

5.1.2.1.1.1 Reading just the value (OPC Classic)

Some applications need the actual data value for further processing (e.g. for computations that need be performed on the values), even if it involves waiting a little for the quality to become **Good**.

In This Topic

A single item

For such usage, call the ReadItemValue method, passing it the same arguments as to the ReadItem method. The method will wait until the OPC item's quality becomes **Good** (or until a timeout expires), and you will receive back an Object (a VARIANT in OPC Data Client-COM) holding the actual data value.

Note: In OPC XML-DA, the ReadItemValue method does not wait for the **Good** quality. It makes a single read, and if the value obtained does not have a **Good** quality, the method returns an error.

C#

```
// This example shows how to read and display value of a single item.
// One of the shortest examples possible.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    class ReadItemValue
    {
        public static void Main1()
        {
            var client = new EasyDAClient();

            Console.WriteLine("Reading item value...");
            object value;
            try
            {
                value = client.ReadItemValue("", "OPCLabs.KitServer.2", "Demo.Ramp");
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message);
                return;
            }

            Console.WriteLine(value);
        }
    }
}
```

PHP

```

```

```
    WScript.Quit
End If
On Error Goto 0
WScript.Echo "value: " & value
```

Multiple items

For reading just the data values of multiple data values (with wait for **Good** quality) in an efficient manner, call the ReadMultipleItemValues method (instead of multiple ReadItemValue calls in a loop). You will receive back an array of ValueResult objects.

Note: In OPC XML-DA, the ReadMultipleItemValues method does not wait for the **Good** quality. It makes a single read, and if the value obtained does not have a **Good** quality, the method returns an error for such an item.

C#

```
// This example shows how to read 4 items at once, and display their values, timestamps and
qualities.

In OPC Data Client.NET, you can pass in a ServerDescriptor object and an array of DAItemDescriptor objects, or an array of DAItemArguments objects, to the ReadMultipleItemValues method.

5.1.2.1.1.2 Reading in OPC XML-DA

In OPC XML-DA, reading or writing is in principle no different from COM-based OPC. You just need to specify the OPC server using its URL instead of the ProgID or CLSID, and obey the rules for identificaton of the items (which are server-dependent). Sometimes, you may need an additional piece of information to identify nodes in OPC XML-DA address space; for more information see **Identifying information in OPC XML (Section 4.10)**.

C#

```
// This example shows how to read 4 items from an OPC XML-DA server at once, and
display their values, timestamps
// and qualities.

using System;
using System.Diagnostics;
using OpcLabs.EasyOpc;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess.Xml
{
    class ReadMultipleItems
    {
        public static void Main1Xml()
        {
            var client = new EasyDAClient();

            DAVtqResult[] vtqResults = client.ReadMultipleItems(
                new ServerDescriptor { UrlString = "http://opcxml.demo-
this.com/XmlDaSampleServer/Service.asmx" },
                new DAItemDescriptor[]
                    {
                        "Dynamic/Analog Types/Double",
                        "Dynamic/Analog Types/Double[]",
                        "Dynamic/Analog Types/Int",
                        "SomeUnknownItem"
                    });

            for (int i = 0; i < vtqResults.Length; i++)
            {
                Debug.Assert(vtqResults[i] != null);

                if (vtqResults[i].Exception != null)
                {
                    Console.WriteLine("vtqResults[{0}] *** Failure: {1}", i,
vtqResults[i].ErrorMessageBrief);
                    continue;
                }
                Console.WriteLine("vtqResults[{0}].Vtq: {1}", i, vtqResults[i].Vtq);

```

5.1.2.1.2 Getting OPC Classic Property Values

Each OPC item has typically associated a set of OPC properties with it. OPC properties contain additional information related to the item.

> ⚠ Except in special cases with clear justification, do not use the OPC Classic property mechanism to get "dynamic" properties such as Value, Quality, or Timestamp. Doing so is very inefficient and has additional issues associated with it (reliability, consistency). Use normal read or subscriptions instead.

In This Topic

A single property

If you want to obtain the value of specific OPC property, call the GetPropertyValue method, passing it the machine name, server class, the ItemId, and a PropertyId. You will receive back an Object (a VARIANT in OPC Data Client-COM) containing the value of the requested property.

C#

```
// This example shows how to get a value of a single OPC property.
//
// Note that some properties may not have a useful value initially (e.g. until the item
is activated in a group), which also the
// case with Timestamp property as implemented by the demo server. This behavior is
server-dependent, and normal. You can run
// IEasyDAClient.ReadItemValue.Main.vbs shortly before this example, in order to obtain
better property values. Your code may
// also subscribe to the item in order to assure that it remains active.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class GetPropertyValue
    {
        public static void Main1()
        {
            var client = new EasyDAClient();

            object value;
            try
            {
                value = client.GetPropertyValue("", "OPCLabs.KitServer.2",
"Simulation.Random",
                    DAPropertyIds.Timestamp);
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }

            Console.WriteLine(value);
        }
    }
}
```

PHP

```
// This example shows how to get a value of a single OPC property.
//
// Note that some properties may not have a useful value initially (e.g. until the item
```

```
is activated in a group), which also the
// case with Timestamp property as implemented by the demo server. This behavior is
server-dependent, and normal. You can run
// IEasyDAClient.ReadItemValue.Main.vbs shortly before this example, in order to obtain
better property values. Your code may
// also subscribe to the item in order to assure that it remains active.

const Timestamp = 4;

$Client = new COM("OpcLabs.EasyOpc.DataAccess.EasyDAClient");

try
{
    $value = $Client->GetPropertyValue("", "OPCLabs.KitServer.2", "Simulation.Random",
Timestamp);
}
catch (com_exception $e)
{
    printf("*** Failure: %s\n", $e->getMessage());
    Exit();
}

printf("%s\n", $value);
```

VB.NET

```
' This example shows how to get a value of a single OPC property.
'
' Note that some properties may not have a useful value initially (e.g. until the item

            Try
                value = client.GetPropertyValue("", "OPCLabs.KitServer.2",
"Simulation.Random", DAPropertyIds.Timestamp)
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message)
                Exit Sub
            End Try

            Console.WriteLine(value)
        End Sub
    End Class
```

```
End Namespace
```

VBScript

```
Rem This example shows how to get a value of a single OPC property.
Rem
Rem Note that some properties may not have a useful value initially (e.g. until the
item is activated in a group), which also the
Rem case with Timestamp property as implemented by the demo server. This behavior is
server-dependent, and normal. You can run
Rem IEasyDAClient.ReadItemValue.Main.vbs shortly before this example, in order to
obtain better property values. Your code may
Rem also subscribe to the item in order to assure that it remains active.

Option Explicit

Const Timestamp = 4

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")

On Error Resume Next
Dim value: value = Client.GetPropertyValue("", "OPCLabs.KitServer.2",
"Simulation.Random", Timestamp)
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0

WScript.Echo value
```

VBScript

```
Rem This example measures the time needed to get values of all OPC properties of a
single OPC item "one by one".

Option Explicit

Dim ServerDescriptor: Set ServerDescriptor =
CreateObject("OpcLabs.EasyOpc.ServerDescriptor")
ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"

Dim NodeDescriptor: Set NodeDescriptor =
CreateObject("OpcLabs.EasyOpc.DataAccess.DANodeDescriptor")
NodeDescriptor.ItemID = "Simulation.ReadValue_I4"

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")

Dim PropertyElementCollection
On Error Resume Next
Set PropertyElementCollection = Client.BrowseProperties(ServerDescriptor,
NodeDescriptor)
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0
```

```
'EasyDAClient.ReadItemValue "", "OPCLabs.KitServer.2", "Simulation.ReadValue_I4"
Dim startTime: startTime = Timer
Dim PropertyElement: For Each PropertyElement In PropertyElementCollection
    Dim propertyID: Set propertyID = PropertyElement.PropertyID
    On Error Resume Next
    Dim value: value = Client.GetPropertyValue("", "OPCLabs.KitServer.2",
"Simulation.ReadValue_I4", propertyID.NumericalValue)
    If Err.Number <> 0 Then
        WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
        WScript.Quit
    End If
    On Error Goto 0
    'WScript.Echo value
Next
WScript.Echo "Time taken (milliseconds): " & (Timer - startTime)*1000
```

The GetPropertyValue Method returns a generic object, regardless of the property involved. You may therefore need to cast the returned value to the expected type, and possibly do further processing on the value, as in the the example below.

C#

```
// This example shows how to obtain a data type of an OPC item.

using System;
using OpcLabs.BaseLib.ComInterop;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class GetPropertyValue
    {
        public static void DataType()
        {
            var client = new EasyDAClient();

            // Get the value of DataType property; it is a 16-bit signed integer
            short dataType;
            try
            {
                dataType = (short)client.GetPropertyValue("", "OPCLabs.KitServer.2",
"Simulation.Random",
                    DAPropertyIds.DataType);
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }
            // Convert the data type to VarType
            var varType = (VarType)dataType;

            // Display the obtained data type
```

```
            Console.WriteLine("DataType: {0}", dataType);    // Display data type as
numerical value
            Console.WriteLine("VarType: {0}", varType);      // Display data type
symbolically

            // Code below illustrates how decisions can be made based on type
            switch (varType.InternalValue)
            {
                case VarTypes.R8:

        End Sub
    End Class
End Namespace
```

In OPC Data Client.NET, you can also pass in the ServerDescriptor inplace of the machine name and server class strings.

In addition to basic methods, there are also many property-related methods. Please refer to a chapter in this document that describes EasyOPC.NET Extensions.

Multiple properties

For obtaining multiple properties simultaneously in an efficient manner, call the GetMultiplePropertyValues method (instead of multiple GetPropertyValue calls in a loop). The arguments are similar, except that in place of a single PropertyId you pass in an array of them. You will receive back an array of Object values (a SAFEARRAY of VARIANT values in OPC Data Client-COM).

OPC Data Access

Object Pascal

```
// This example shows how to get value of multiple OPC properties.
//
// Note that some properties may not have a useful value initially (e.g. until the item
is activated in a group), which also the
// case with Timestamp property as implemented by the demo server. This behavior is
server-dependent, and normal. You can run
// IEasyDAClient.ReadMultipleItemValues.Main.vbs shortly before this example, in order
to obtain better property values. Your
// code may also subscribe to the items in order to assure that they remain active.

5.1.2.1.3 Reading Attributes of OPC UA Nodes

In OPC UA Data Access, reading data from attributes of OPC nodes is one of the most common tasks. The OPC server generally provides data for any OPC attribute in form of a Value, Timestamps and Status Code combination (see chapter "OPC Attribute Data").

In This Topic

A single node and attribute

If you want to read the current attribute data from an attribute of an OPC node, call the Read method. You pass in individual arguments for the endpoint descriptor and the node ID. You will receive back a UAAttributeData object holding the current value, timestamps, and status code for the specified OPC node and attribute. The Read method returns the current attribute data, regardless of the actual status code. You may receive an Uncertain or even Bad status (and no usable data value), and your code needs to deal with such situations accordingly.

C#

```
// This example shows how to read and display data of an attribute (value, timestamps,
and status code).

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    class Read
    {
        public static void Main1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)

```

If the attribute ID is not specified in the method call, the method will read from the **Value** attribute. There are also other overloads of the Read method that allow you to pass in the arguments in a different way, and with more information in them. For example, you can pass in a UANodeArguments object, and an attribute ID.

Multiple nodes or attributes

For reading attribute data of multiple attributes (of the same node or of different nodes) simultaneously in an efficient manner, call the ReadMultiple method (instead of multiple Read calls in a loop). You pass in an array of UAReadArguments objects, and you will receive back an array of UAAttributeDataResult objects.

C#

```
// This example shows how to read data (value, timestamps, and status code) of 3
attributes at once. In this example,
// we are reading a Value attribute of 3 different nodes, but the method can also be
used to read multiple attributes
// of the same node.

Read parameters

It is possible to specify the maximum age of the value to be read. In order to do that, set the MaximumAge property of UAReadArguments.ReadParameters object passed to the read method, to the appropriate number of milliseconds. By default, this property is set to UAReadParameters.FromCache, which denotes reading from the cache.

Note: OPC “Classic” has separate functions for reading so-called OPC properties. OPC properties contain additional information related to a node. In OPC Unified Architecture, properties are accessed in the same way as other information. That is, if you have a node ID (obtain e.g. by browsing) of a property, you can use one of the ReadXXXX methods described in this chapter to get a value of that property.

Using browse paths

C#

```
// This example shows how to read the attributes of 4 OPC-UA nodes specified by browse
paths at once, and display the
// results.
```

```

5.1.2.1.3.1 Reading just the value (OPC UA)

Some applications need the actual data value for further processing (e.g. for computations that need be performed on the values), i.e. the status code must be Good and a valid value must be provided by the server, otherwise it is considered an error.

In This Topic

A single node and attribute

For such usage, call the ReadValue method, passing it the same arguments as to the Read method. The method will read the attribute data, check if the status is Good, and you will receive back an Object holding the actual data value. If the status code is not Good, the method will throw a UAStatusCodeException.

C#

```
// This example shows how to read value of a single node, and display it.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;
```

```
namespace UADocExamples._EasyUAClient
{
    partial class ReadValue
    {
        public static void Overload1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object
            var client = new EasyUAClient();

            // Obtain value of a node
            object value;
            try

Multiple nodes or attributes

For reading just the data values of multiple data values (with Good status) in an efficient manner, call the ReadMultipleValues method (instead of multiple ReadValue calls in a loop). You pass in an array of UAReadArguments objects, and you will receive back an array of ValueResult objects.

C#

```
// This example shows how to read the Value attributes of 3 different nodes at once. Using the same
method, it is also possible
// to read multiple attributes of the same node.

using System;
using OpcLabs.BaseLib.OperationModel;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    partial class ReadMultipleValues
    {
        public static void Main1()
        {
```

```
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object
            var client = new EasyUAClient();

            // Obtain values. By default, the Value attributes of the nodes will be read.
            ValueResult[] valueResultArray = client.ReadMultipleValues(new[]
                {
                    new UAReadArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10845"),
                    new UAReadArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10853"),
                    new UAReadArguments(endpointDescriptor, "nsu=http://test.org/UA/Data/;i=10855")
                });

            // Display results
            foreach (ValueResult valueResult in valueResultArray)
            {
                if (valueResult.Succeeded)
                    Console.WriteLine("Value: {0}", valueResult.Value);
                else
                    Console.WriteLine("*** Failure: {0}", valueResult.ErrorMessageBrief);
            }

            // Example output:
            //
            //Value: 8
            //Value: -8.06803E+21
            //Value: Strawberry Pig Banana Snake Mango Purple Grape Monkey Purple? Blueberry Lemon^
        }
    }
}
```

5.1.2.2 Modifying Information (OPC Data)

Methods described in this chapter allow your application to modify information in the underlying data source that the OPC server connects to (writing OPC Classic items, or attributes of OPC UA nodes). It is assumed that your application already somehow knows how to identify the data it is interested in. If the location of the data is not known upfront, use methods described Browsing for Information chapter first.

5.1.2.2.1 Writing to OPC Classic Items

A single item

If you want to write a data value into a specific OPC item, call the WriteItemValue method, passing it the data value you want to write, arguments for machine name, server class, ItemID, and an optional data type.

C#

```
// This example shows how to write a value into a single item.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class WriteItemValue
    {
        public static void Main1()
        {
            var client = new EasyDAClient();

            try
            {
                client.WriteItemValue("", "OPCLabs.KitServer.2", "Simulation.Register_I4", 12345);
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message);
            }
        }
    }
}
```

PHP

```
// This example shows how to write a value into a single item.

$Client = new COM("OpcLabs.EasyOpc.DataAccess.EasyDAClient");

try
```

```
{
    $value = $Client->WriteItemValue("", "OPCLabs.KitServer.2", "Simulation.Register_I4", 12345);
}
catch (com_exception $e)
{
    printf("*** Failure: %s\n", $e->getMessage());
    Exit();
}
```

VB.NET

```
' Shows how to write into an OPC item that is of array type, and read the array value back.

Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess._EasyDAClient
    Partial Friend Class WriteItemValue
        Public Shared Sub Main1()
            Dim client = New EasyDAClient()

            Try
                client.WriteItemValue("", "OPCLabs.KitServer.2", "Simulation.Register_I4", 12345)
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message)
                Exit Sub
            End Try
        End Sub
    End Class
End Namespace
```

Object Pascal

```
// This example shows how to write a value into a single item.

class procedure WriteItemValue.Main;
var
  Client: OpcLabs_EasyOpcClassic_TLB._EasyDAClient;
begin
  // Instantiate the client object
  Client := CoEasyDAClient.Create;

  try
    Client.WriteItemValue('', 'OPCLabs.KitServer.2', 'Simulation.Register_I4', 12345);
  except
    on E: EOleException do
    begin
      WriteLn(Format('*** Failure: %s', [E.GetBaseException.Message]));
      Exit;
    end;
  end;

end;
```

PowerScript

```
// This example shows how to write a value into a single item.

mle_outputtext.Text = ""

// Instantiate the client object
OLEObject client
client = CREATE OLEObject
client.ConnectToNewObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")

// Modify value of an item
```

```
TRY
    client.WriteItemValue("", "OPCLabs.KitServer.2", "Simulation.Register_I4", 12345)
CATCH (OLERuntimeError oleRuntimeError)
    mle_outputtext.Text = mle_outputtext.Text + "*** Failure: " + oleRuntimeError.Description + "~r~n"
    RETURN
END TRY

mle_outputtext.Text = mle_outputtext.Text + "~r~n"
mle_outputtext.Text = mle_outputtext.Text + "Finished." + "~r~n"
```

VBScript

```
Rem This example shows how to write a value into a single item.

Option Explicit

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
On Error Resume Next
Client.WriteItemValue "", "OPCLabs.KitServer.2", "Simulation.Register_I4", 12345
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0
```

In OPC Data Client.NET, you can also pass in the ServerDescriptor and DAItemDescriptor objects in place of corresponding individual arguments.

C#

```
// This example shows how to write a value into a single OPC XML-DA item.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess.Xml
{
    class WriteItemValue
    {
        public static void Main1Xml()
        {
            var client = new EasyDAClient();

            try
            {
                client.WriteItemValue("http://opcxml.demo-this.com/XmlDaSampleServer/Service.asmx",
"Static/Analog Types/Int", 12345);
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message);
            }
        }
    }
}
```

VB.NET

```
' This example shows how to write a value into a single OPC XML-DA item.

Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess.Xml
```

```
    Partial Friend Class WriteItemValue
        Public Shared Sub Main1Xml()
            Dim client = New EasyDAClient()

            Try
                client.WriteItemValue("http://opcxml.demo-this.com/XmlDaSampleServer/Service.asmx",
"Static/Analog Types/Int", 12345)
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}", opcException.GetBaseException().Message)
                Exit Sub
            End Try
        End Sub
    End Class
End Namespace
```

Multiple items

For writing data values into multiple OPC items in an efficient manner, call the WriteMultipleItemValues method.

In OPC Data Client.NET, you pass in an array of DAItemValueArguments objects, each specifying the location of OPC item, and the value to be written.

For an efficient writing into several items, use the WriteMultipleItemValues method.

C#

```
// Shows how to write into multiple OPC items using a single method call, and read multiple item values
back.

using System;
using System.Diagnostics;
using OpcLabs.BaseLib.OperationModel;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class WriteMultipleItemValues
    {
        public static void Main1()
        {
            var client = new EasyDAClient();

            Console.WriteLine("Writing multiple item values...");
            OperationResult[] resultArray = client.WriteMultipleItemValues(
                new[] {
                    new DAItemValueArguments("", "OPCLabs.KitServer.2", "Simulation.Register_I4",
12345),
                    new DAItemValueArguments("", "OPCLabs.KitServer.2", "Simulation.Register_BOOL",
true),
                    new DAItemValueArguments("", "OPCLabs.KitServer.2", "Simulation.Register_R4",
234.56)
                });

            for (int i = 0; i < resultArray.Length; i++)
            {
                Debug.Assert(resultArray[i] != null);
                if (resultArray[i].Succeeded)
                    Console.WriteLine("Result {0}: success", i);
                else
                {
                    Debug.Assert(resultArray[i].Exception != null);
                    Console.WriteLine("Result {0} *** Failure: {1}", i,
resultArray[i].ErrorMessageBrief);
```

```
            }
        }

        Console.WriteLine("Reading multiple item values...");
        ValueResult[] valueResultArray = client.ReadMultipleItemValues("OPCLabs.KitServer.2",
            new DAItemDescriptor[] {
                    "Simulation.Register_I4",
                    "Simulation.Register_BOOL",
                    "Simulation.Register_R4" });

Advanced topics

If you need to write a combination of value, timestamps, and status code be written, and your OPC server support this, see **Writing value, timestamps and status code (OPC UA) (Section 5.1.2.2.2.3)**.

5.1.2.2.1.1 Writing value, timestamp and quality (OPC Classic)

Some newer OPC servers allow a combination of value, timestamp, and quality (VTQ) be written into their items.

If you need to do this, call WriteItem or WriteMultipleItems method.

In This Topic

A single item

Object Pascal

```
// This example shows how to write a value, timestamp and quality into a single item.

class procedure WriteItem.Main;
var
  Client: OpcLabs_EasyOpcClassic_TLB._EasyDAClient;
begin
  // Instantiate the client object
  Client := CoEasyDAClient.Create;

  try
    Client.WriteItem('', 'OPCLabs.KitServer.2', 'Simulation.Register_I4', 12345,
EncodeDate(1980, 1, 1), DAQualities_GoodNonSpecific);
  except
    on E: EOleException do
    begin
      WriteLn(Format('*** Failure: %s', [E.GetBaseException.Message]));
      Exit;
    end;
  end;

end;
```

VBScript

```
Rem This example shows how to write a value, timestamp and quality into a single item.

Option Explicit

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
On Error Resume Next
Client.WriteItem "", "OPCLabs.KitServer.2", "Simulation.Register_I4", 12345,
DateSerial(1980, 1, 1), 192
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0
```

Multiple items

Object Pascal

```
// This example shows how to write values, timestamps and qualities into 3 items at
once.

class procedure WriteMultipleItems.Main;
var
  Arguments: OleVariant;
  Client: OpcLabs_EasyOpcClassic_TLB._EasyDAClient;
  I: Cardinal;
  ItemVtqArguments1: _DAItemVtqArguments;

Dim i: For i = LBound(results) To UBound(results)
    Dim OperationResult: Set OperationResult = results(i)
    If OperationResult.Succeeded Then
        WScript.Echo "Result " & i & ": success"
    Else
        WScript.Echo "Result " & i & ": " &
OperationResult.Exception.GetBaseException.Message
    End If
Next
```

More...

You can also specify the requested data type when writing the value, timestamp and quality. See **Data Type in OPC Classic Write (Section 5.1.2.2.1.2)**.

5.1.2.2.1.2 Data Type in OPC Classic Write

With some OPC servers or usage cases, it may be needed to specify the requested data type when writing into the item. Reasons for that may be e.g.:

- The OPC server uses some unusual communication method which prevents it from determining the proper canonical data type for the item.
- The OPC server is written in a special way that allows a different behavior based on the concrete data type requested.
- The OPC server may be capable of automatically creating new items when they are requested, and needs the requested data type in order to create the item properly.

In such cases you can pass the requested data type to the OPC server during writing.

In This Topic

A single item

There is an overload of the WriteItemValue extension method that allows you to pass in the requested data type.

C#

```
// This example shows how to write a value into a single item, specifying its requested
data type.

using System;
using OpcLabs.BaseLib.ComInterop;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class WriteItemValue
    {
        public static void RequestedDataType()
        {
            var client = new EasyDAClient();

            try
            {
                client.WriteItemValue("", "OPCLabs.KitServer.2",
"Simulation.Register_I4", 12345,
                    VarTypes.I4);   // <-- the requested data type
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
            }
        }
    }
}
```

VB.NET

```
' This example shows how to write a value into a single item, specifying its requested
data type.

Imports OpcLabs.BaseLib.ComInterop
Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess._EasyDAClient
    Partial Friend Class WriteItemValue
        Public Shared Sub RequestedDataType()
            Dim client = New EasyDAClient()

            Try
                client.WriteItemValue("", "OPCLabs.KitServer.2",
"Simulation.Register_I4", 12345,
                                      VarTypes.I4) ' <-- the requested data type
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message)
                Exit Sub
            End Try
```

```
        End Sub
    End Class
End Namespace
```

Multiple items

The DAItemValueArguments objects that you pass to the WriteMultipleItemValues method contain an ItemDescriptor, in which you can modify the RequestedDataType property as needed.

C#

```
// Shows how to write into multiple OPC items using a single method call, specifying
their requested data types.

using System;
using System.Diagnostics;
using OpcLabs.BaseLib.ComInterop;
using OpcLabs.BaseLib.OperationModel;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class WriteMultipleItemValues
    {
        public static void RequestedDataType()
        {
            var client = new EasyDAClient();

            Console.WriteLine("Writing multiple item values...");
            OperationResult[] resultArray = client.WriteMultipleItemValues(new[] {
                    new DAItemValueArguments("", "OPCLabs.KitServer.2",
"Simulation.Register_I2", 12345)
                        { ItemDescriptor = { RequestedDataType = VarTypes.I2}}, // <--
the requested data type
                    new DAItemValueArguments("", "OPCLabs.KitServer.2",
"Simulation.Register_R4", 234.56)
                        { ItemDescriptor = { RequestedDataType = VarTypes.R4}}  // <--
the requested data type
                });

            for (int i = 0; i < resultArray.Length; i++)
            {
                Debug.Assert(resultArray[i] != null);
                if (resultArray[i].Succeeded)
                    Console.WriteLine("Result {0}: success", i);
                else
                {
                    Debug.Assert(resultArray[i].Exception != null);
                    Console.WriteLine("Result {0} *** Failure: {1}", i,
resultArray[i].ErrorMessageBrief);
```

```
            }
        }

        Console.WriteLine("Reading multiple item values...");
        ValueResult[] valueResultArray =
client.ReadMultipleItemValues("OPCLabs.KitServer.2",
            new DAItemDescriptor[] { "Simulation.Register_I2",
"Simulation.Register_R4" });

        for (int i = 0; i < valueResultArray.Length; i++)
        {
            Debug.Assert(valueResultArray[i] != null);
            Console.WriteLine("valueResultArray[{0}]: {1}", i,
valueResultArray[i]);
        }
    }
  }
}
```

VB.NET

```
' Shows how to write into multiple OPC items using a single method call, specifying
their requested data types.

Imports OpcLabs.BaseLib.ComInterop
Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.DataAccess.OperationModel

Namespace DocExamples.DataAccess._EasyDAClient
    Partial Friend Class WriteMultipleItemValues
        Public Shared Sub RequestedDataType()

VarTypes.R4}} _
            })

            For i = 0 To resultArray.Length - 1
                Debug.Assert(resultArray(i) IsNot Nothing)
                If resultArray(i).Succeeded Then
                    Console.WriteLine("Result {0}: success", i)
                Else
                    Debug.Assert(resultArray(i).Exception IsNot Nothing)
                    Console.WriteLine("Result {0} *** Failure: {1}", i,
resultArray(i).ErrorMessageBrief)
                End If
            Next i
```

```
            Console.WriteLine("Reading multiple item values...")
            Dim valueResultArray = client.ReadMultipleItemValues("OPCLabs.KitServer.2",
                    New DAItemDescriptor() {"Simulation.Register_I2",
"Simulation.Register_R4"})

            For i = 0 To valueResultArray.Length - 1
                Debug.Assert(valueResultArray(i) IsNot Nothing)
                Console.WriteLine("valueResultArray[{0}]: {1}", i, valueResultArray(i))
            Next i
        End Sub
    End Class
End Namespace
```

More...

Specifying the data type is also possible, in a similar manner, when **Writing value, timestamp and quality (OPC Classic) (Section 5.1.2.2.1.1)**.

5.1.2.2.2 Writing Attributes of OPC UA Nodes

A single node and attribute

If you want to write a data value into an attribute of a specific node in OPC UA, call the WriteValue method, passing it the data value you want to write, arguments for endpoint descriptor, node ID, and an optional data type.

In This Topic

C#

```
// This example shows how to write a value into a single node.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    partial class WriteValue
    {
        public static void Main1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object
            var client = new EasyUAClient();

            // Modify value of a node
```

```
            try
            {
                client.WriteValue(endpointDescriptor, "nsu=http://test.org/UA/Data/;i=10221",
12345);
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}", uaException.GetBaseException().Message);
            }
        }
    }
}
```

VB.NET

```
' This example shows how to write a value into a single node.

Imports OpcLabs.EasyOpc.UA
Imports OpcLabs.EasyOpc.UA.OperationModel

Namespace UADocExamples._EasyUAClient
    Partial Friend Class WriteValue
        Public Shared Sub Main1()

            ' Define which server we will work with.
            Dim endpointDescriptor As UAEndpointDescriptor =
                    "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer"
            ' or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            ' or "https://opcua.demo-this.com:51212/UA/SampleServer/"

On Error Goto 0
```

When you specify individual arguments to the simplest overload of the WriteValue method, the method will write to the **Value** attribute of the node, and if the value type is an array, it will modify the whole contents of that array. If you want to write into a different attribute, or write only to a subset of an array, use one of the more complex overloads of the WriteValue method, such as with an argument of UAWriteValueArguments type, and fill this argument will all necessary information.

Multiple nodes or attributes

For writing data values into multiple OPC attributes (in the same or different nodes) in an efficient manner, call the WriteMultipleValues method. You pass in an array of UAWriteValueArgument objects, each specifying the location of OPC node, attribute, and the value to be written.

C#

```
// This example shows how to write values into 3 nodes at once.

using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    partial class WriteMultipleValues
    {
        public static void Main1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object
            var client = new EasyUAClient();

            // Modify value of a node
            client.WriteMultipleValues(new[]
                {
                    new UAWriteValueArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10221", 23456),
                    new UAWriteValueArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10226", 2.34567890),
                    new UAWriteValueArguments(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10227", "ABC")
                });
```

```
            // Production code would check the success of the operation. See separate example for
that.
        }
    }
}
```

VB.NET

```
' This example shows how to write values into 3 nodes at once.

Imports OpcLabs.EasyOpc.UA
Imports OpcLabs.EasyOpc.UA.OperationModel

Namespace UADocExamples._EasyUAClient
    Partial Friend Class WriteMultipleValues
        Public Shared Sub Main1()

            ' Define which server we will work with.

    End If
Next
```

Write results

The WriteMultiple and WriteMultipleValues methods return an array of UAWriteResult objects. Besides the inherited members of OperationResult, such as the Exception, the UAWriteResult contains additional information that describes the outcome of the Write operation in case of success:

- The Clamped flag: Determines whether the value written was accepted but was clamped.

- The CompletesAsynchronously flag: Determines whether the processing will complete asynchronously.

5.1.2.2.2.1 Data Type in OPC UA Write

The value written needs to be of correct type, and the data type needs to be passed to the OPC-UA server together with the value.

OPC Data Client-UA processes the value and data type in following steps:

1. Determine the (CLS-compliant) .NET data type. If you are writing to an attribute other than the **Value** attribute, the component uses the data type of that attribute as given by the OPC-UA specification, because of these attributes, the data types are fixed.

   Wherever the **Value** attribute is being written (which is the most common case), and your code has not provided a specific value type, the data type is resolved from the OPC-UA server by reading the **DataType** and **ValueRank** attributes of the same node. This is because the type of **Value** attribute can differ with each node.

   When the data type of the node is not among the standard data types defined in OPC UA, attempts to find its supertype, by following the appropriate reference in the server's address space. This process is repeated if needed, until a known data type is found, or the supertype cannot be determined.

2. The value that comes from your code is converted to the (CLS-compliant) .NET data type determined in previous step.
3. Determine the OPC-UA built-in type for the attribute being written.
4. If needed, the type of the value is changed to the OPC-UA built-in type determined in the previous step.

As you can see, not specifying the value type is convenient, but causes additional Read and possibly Browse operations on the OPC-UA server in Step 1. This can have negative performance implications. You can prevent the additional Reads with **Value** attribute by specifying the value type explicitly. When you do so, you must be careful to specify the correct type. For example, if you pass in a value of 199 and specify the value type as a signed integer (Int32 in .NET), OPC Data Client will send the value and corresponding type ID to the OPC-UA server as a signed integer. If the server expects a value that must be an unsigned integer, even though the value is otherwise correct (and also non-negative), an error can occur.

How do you specify the value type in your code? This depends on the type of method you are calling. Some methods accept individual arguments, and they have overloads with either valueType or valueTypeCode argument. Other methods accept UAWriteArguments or UAWriteValueArguments object; in this case, you specify the value type by properly setting the ValueType or ValueTypeCode property in this object. There is also a ValueTypeFullName property, which is a string form of the ValueType property. Its use is mainly from COM languages, where the .NET Type is not easily accessible.

The TypeCode can be used for basic, simple types. For more complex types, such as arrays, you need to specify the .NET Type.

When the value type is a null reference, or the value type code is TypeCode.Empty, it means that the value type is not specified, and the component will determine it by interrogating the OPC-UA server, as described at the beginning of the article.

Examples

The example below writes a single value, specifying the type to be written using a .NET Type.

Note that this example uses an overload of the WriteValue method that is not available in COM. If you are calling from a COM language or tool, use the WriteMultipleValues method instead. An example for that is given further down.

C#

```
// This example shows how to write a value into a single node, specifying a type
explicitly.
//
// Reasons for specifying the type explicitly might be:
// - The data type in the server has subtypes, and the client therefore needs to pick
the subtype to be written.
// - The data type that the server reports is incorrect.
// - Writing with an explicitly specified type is more efficient.
//
// For a selected subset of most common types, you can also use a different overload of
the WriteValue method, and specify
// a value from the TypeCode enumeration instead.

The example below writes multiple values, specifying the types to be written in the ValueType property, using a .NET Type.

Note that this approach is, at least theoretically, also available in COM languages and tools, but due to difficulties with obtaining the .NET Type, you are much more likely to specify the type using the ValueTypeCode or ValueTypeFullName property, for which the examples are given further down.

C#

```
// This example shows how to write values into 3 nodes at once, specifying a type
explicitly. It tests for success of each
// write and displays the exception message in case of failure.
//
// Reasons for specifying the type explicitly might be:
// - The data type in the server has subtypes, and the client therefore needs to pick
the subtype to be written.
// - The data type that the reports is incorrect.
// - Writing with an explicitly specified type is more efficient.
//
// Alternative ways of specifying the type are using the ValueTypeCode or
ValueTypeFullName properties.

End Namespace
```

The example below writes multiple values, specifying the types to be written in the ValueTypeCode property, using a TypeCode.

This approach is suitable for a basic set of types covered by the TypeCode enumeration, and is also accessible to COM languages and tools. If you need to specify a type that is not covered by the TypeCode enumeration, use the ValueType or ValueTypeFullName property instead.

C#

```
// This example shows how to write values into 3 nodes at once, specifying a type code
explicitly. It tests for success of
// each write and displays the exception message in case of failure.
//
// Reasons for specifying the type explicitly might be:
// - The data type in the server has subtypes, and the client therefore needs to pick
the subtype to be written.
// - The data type that the reports is incorrect.
// - Writing with an explicitly specified type is more efficient.
//
// Alternative ways of specifying the type are using the ValueType or ValueTypeFullName
properties.

The example below writes multiple values, specifying the types to be written in the ValueTypeFullName property, using a string form of the .NET Type.

This approach is especially suitable in COM languages and tools, if you need to specify a type that is not covered by the TypeCode enumeration.

C#

```
// This example shows how to write values into 3 nodes at once, specifying a type's
full name explicitly. It tests for
// success of each write and displays the exception message in case of failure.
//
// Reasons for specifying the type explicitly might be:
// - The data type in the server has subtypes, and the client therefore needs to pick
the subtype to be written.
// - The data type that the reports is incorrect.
// - Writing with an explicitly specified type is more efficient.
//
// Alternative ways of specifying the type are using the ValueType or ValueTypeCode
properties.

```

5.1.2.2.2.3 Writing value, timestamps and status code (OPC UA)

Some OPC servers allow a combination of value, timestamps, and status code be written into their nodes (or to some nodes only). If you need to do this, call Write or WriteMultiple method.

A single node and attribute

C#

```
// This example shows how to write data (a value, timestamps and status code) into a
single attribute of a node.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    class Write
    {
        public static void Main1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object
            var client = new EasyUAClient();

            try
            {
                // Modify data of a node's attribute
                client.Write(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10221",
                    new UAAttributeData(12345, UASeverity.GoodOrSuccess,
DateTime.UtcNow));

                // The target server may not support this, and in such case a failure
will occur.
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message);
            }
        }
    }
}
```

VB.NET

```
' This example shows how to write data (a value, timestamps and status code) into a
single attribute of a node.
```

```
Imports OpcLabs.EasyOpc.UA
Imports OpcLabs.EasyOpc.UA.OperationModel

Namespace UADocExamples._EasyUAClient
    Friend Class Write
        Public Shared Sub Main1()

            ' Define which server we will work with.
            Dim endpointDescriptor As UAEndpointDescriptor =
                    "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer"
            ' or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET

                                        New UAAttributeData(12345, UASeverity.GoodOrSuccess,
Date.UtcNow)) ' or "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer"

                ' The target server may not support this, and in such case a failure
will occur.
            Catch uaException As UAException
                Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message)
            End Try
        End Sub
    End Class
End Namespace
```

PHP

```
// This example shows how to write data (a value, timestamps and status code) into a
single attribute of a node.

$GoodOrSuccess = 0;

// Instantiate the client object
$Client = new COM("OpcLabs.EasyOpc.UA.EasyUAClient");

// Modify data of a node's attribute
$StatusCode = new COM("OpcLabs.EasyOpc.UA.UAStatusCode");
$StatusCode->Severity = $GoodOrSuccess;
$AttributeData = new COM("OpcLabs.EasyOpc.UA.UAAttributeData");
$AttributeData->Value = 12345;
$AttributeData->StatusCode = $StatusCode;
$AttributeData->SourceTimestamp = (time() - 25569)/86400.0;

// Perform the operation
try
{
    $Client->Write(
```

```
        "http://opcua.demo-this.com:51211/UA/SampleServer", // or
"opc.tcp://opcua.demo-this.com:51210/UA/SampleServer"
        "nsu=http://test.org/UA/Data/;i=10221",
        $AttributeData);
    // The target server may not support this, and in such case a failure will occur.
}
catch (com_exception $e)
{
    printf("*** Failure: %s\n", $e->getMessage());
}
```

VBScript

```
Rem This example shows how to write data (a value, timestamps and status code) into a
single attribute of a node.

Option Explicit

Const GoodOrSuccess = 0

' Instantiate the client object
Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.UA.EasyUAClient")

' Modify data of a node's attribute
Dim StatusCode: Set StatusCode = CreateObject("OpcLabs.EasyOpc.UA.UAStatusCode")
StatusCode.Severity = GoodOrSuccess
Dim AttributeData: Set AttributeData =
CreateObject("OpcLabs.EasyOpc.UA.UAAttributeData")
AttributeData.Value = 12345
AttributeData.StatusCode = StatusCode
AttributeData.SourceTimestamp = Now

' Perform the operation
On Error Resume Next
Client.Write "http://opcua.demo-this.com:51211/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=10221", _
            AttributeData ' or "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer"
' The target server may not support this, and in such case a failure will occur.
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0
```

Multiple nodes or attributes

It is more efficient to use the WriteMultiple method, instead of several calls to the Write method.

C#

```
// This example shows how to write data (a value, timestamps and status code) into 3
nodes at once, test for success of each
```

```
// write and display the exception message in case of failure.

using System;
using OpcLabs.BaseLib.OperationModel;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient

5.1.2.3 Browsing for Information (OPC Data)

OPC Data Client contains methods that allow your application to retrieve and enumerate information about OPC servers that exist on the network, and data available within these servers. Your code can then make use of the information obtained, e.g. to accommodate to configuration changes dynamically.

Note that if you just want to allow your user to browse interactively for various OPC elements, you can simply code your application to invoke the common dialogs that are already implemented in OPC Data Client (they are described further down in this text).

The methods we are describing in this chapter are for programmatic browsing, with no user interface (or when you provide the user interface by your own code).

5.1.2.3.1 Browsing for OPC Classic Servers

If you want to retrieve a list of OPC Data Access servers registered on a local or remote computer, call the BrowseServers method, passing it the name or address of the remote machine (use empty string for local computer).

In OPC Data Client.NET, you will receive back a ServerElementCollection object. If you want to connect to this OPC server later in your code by calling other methods, use the built-in conversion of ServerElement to a String or ServerDescriptor, and pass the resulting string as a serverClass or a serverUrl argument either directly to the method call, or to a constructor of ServerDescriptor object.

In OPC Data Client-COM, if you want to connect to some OPC server later in your code by calling other methods, obtain the value of ServerElement.ServerClass property, and pass the resulting string as a serverClass argument to the method call that accepts it.

Each ServerElement contains information gathered about one OPC server found on the specified machine, including things like the server's CLSID, ProgID, vendor name, and readable description. For an OPC XML server, it contains its URL.

JScript

```
// This example shows how to obtain all ProgIDs of all OPC Data Access servers on the
local machine.

var Client = new ActiveXObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient");
var ServerElements = Client.BrowseServers("")

for (var objEnum = new Enumerator(ServerElements) ; !objEnum.atEnd() ;
objEnum.moveNext()) {
    var ServerElement = objEnum.item();
    WScript.Echo("ServerElements(\"" + ServerElement.UrlString + "\").ProgId: " +
ServerElement.ProgId);
}
```

PHP

```
// This example shows how to obtain all ProgIDs of all OPC Data Access servers on the
local machine.

$Client = new COM("OpcLabs.EasyOpc.DataAccess.EasyDAClient");

try
{
    $ServerElements = $Client->BrowseServers("");
}
catch (com_exception $e)
{
    printf("*** Failure: %s\n", $e->getMessage());
    Exit();
}

foreach ($ServerElements as $ServerElement)
{
    printf("ServerElements(\"%s\").ProgId: %s\n", $ServerElement->ClsidString,
$ServerElement->ProgId);
}
```

VBScript

```
Rem This example shows how to obtain all ProgIDs of all OPC Data Access servers on the
local machine.

    End With
Next
```

5.1.2.3.2 Browsing for OPC Classic Nodes (Branches and Leaves)

OPC Address Space Organization

Items in an OPC server are typically organized in a tree hierarchy (address space), where the branch nodes serve organizational purposes (similar to folders in a file system), while the leaf nodes correspond to actual pieces of data that can be accessed (similar to files in a file system) – the OPC items. Each node has a “short” name that is unique among other branches or leaves under the same parent branch (or a root). Leaf nodes can be fully identified using a “long” ItemID, which determines the OPC item without a need to further qualify it with its position in the tree. ItemIDs may look like “Device1.Block101.Setpoint”, however their syntax and meaning is fully determined by the particular OPC server they are coming from.

In This Topic

Browse Methods

OPC Data Client gives you methods to traverse through the address space information and obtain the information available there. It is also possible to filter the returned nodes by various criteria, such as node name matching certain pattern, or a particular data type only, or writeable items only, etc.

If you want to retrieve a list of all sub-branches under a given branch (or under a root) of the OPC server, call the BrowseBranches method. You will receive back a DANodeElementCollection object. Each DANodeElement contains information gathered about one sub-branch node, such as its name, or indication whether it has children.

VBScript

```
Rem This example shows how to obtain all branches at the root of the address space. For
each branch, it displays whether
Rem it may have child nodes.

Option Explicit

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
On Error Resume Next
Dim BranchElements: Set BranchElements = Client.BrowseBranches("",
"OPCLabs.KitServer.2", "")
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0

Dim BranchElement: For Each BranchElement In BranchElements
    WScript.Echo "BranchElements(""" & BranchElement.Name & """).HasChildren: " &
BranchElement.HasChildren
Next
```

Similarly, if you want to retrieve a list of leaves under a given branch (or under a root) of the OPC server, call the BrowseLeaves method. You will also receive back a DANodeElementCollection object, this time containing the leaves only. You can find information such as the Item ID from the DANodeElement of any leaf, and pass it further to methods like ReadItem or SubscribeItem.

VBScript

```
Rem This example shows how to obtain all leaves under the "Simulation" branch of the
address space. For each leaf, it displays
Rem the ItemID of the node.

Option Explicit

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
On Error Resume Next
Dim LeafElements: Set LeafElements = Client.BrowseLeaves("", "OPCLabs.KitServer.2",
"Simulation")
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
```

```
    WScript.Quit
End If
On Error Goto 0

Dim LeafElement: For Each LeafElement In LeafElements
    WScript.Echo "LeafElements(""" & LeafElement.Name & """).ItemId: " &
LeafElement.ItemId
Next
```

The most generic address space browsing method is BrowseNodes. It combines the functionality of BrowseBranches and BrowseLeaves, and it also allows the widest range of filtering options by passing in an argument of type DABrowseParameters, or individual arguments for data type filter and access rights filter.

Object Pascal

```
// This example shows how to obtain all nodes under the "Simulation" branch of the
address space. For each node, it displays
// whether the node is a branch or a leaf.

class procedure BrowseNodes.Main;
var
  BrowseParameters: _DABrowseParameters;

  NodeElement: _DANodeElement;
  NodeElementEnumerator: IEnumVariant;
  NodeElements: _DANodeElementCollection;
begin
  ServerDescriptor := CoServerDescriptor.Create;
  ServerDescriptor.ServerClass := 'OPCLabs.KitServer.2';

  NodeDescriptor := CoDANodeDescriptor.Create;
  NodeDescriptor.ItemId := 'Simulation';

  BrowseParameters := CoDABrowseParameters.Create;

  // Instantiate the client object
  Client := CoEasyDAClient.Create;

  try
    NodeElements := Client.BrowseNodes(
      ServerDescriptor,
      NodeDescriptor,
      BrowseParameters);
  except
    on E: EOleException do
    begin
      WriteLn(Format('*** Failure: %s', [E.GetBaseException.Message]));
      Exit;
    end;
  end;
```

```
  NodeElementEnumerator := NodeElements.GetEnumerator;
  while (NodeElementEnumerator.Next(1, Element, Count) = S_OK) do
  begin
    NodeElement := IUnknown(Element) as _DANodeElement;
//    WriteLn(NodeElement.Name, ': ', NodeElement.ItemId);
    WriteLn('BrowseElements("', NodeElement.Name, '"):');
    WriteLn('    .IsBranch: ', NodeElement.IsBranch);
    WriteLn('    .IsLeaf: ', NodeElement.IsLeaf);
  end;
end;
```

PHP

```
// This example shows how to obtain all nodes under the "Simulation" branch of the
address space. For each node, it displays
// whether the node is a branch or a leaf.

$ServerDescriptor = new COM("OpcLabs.EasyOpc.ServerDescriptor");
$ServerDescriptor->ServerClass = "OPCLabs.KitServer.2";

5.1.2.3.3 Browsing for OPC Classic Access Paths

> Access paths are somewhat obsolete feature of OPC Data Access specification, and few OPC servers actually use it; but if a particular OPC server does use access paths, specifying the proper access path together with ItemID may be the only way to retrieve the data you want.

If you want to retrieve a list of possible access paths available for a specific OPC item, call the BrowseAccessPaths method, passing it the information about the OPC server, and the ItemID. You will receive back an array of strings; each element of this array is an access path that you can use with methods such as ReadItem or SubscribeItem.

In OPC Data Client.NET, you can also pass the access path to a constructor of DAItemDescriptor object and later use that descriptor with various methods.

VBScript

```
Rem This example shows how to obtain all access paths available for an item.

Option Explicit

Dim ServerDescriptor: Set ServerDescriptor =
CreateObject("OpcLabs.EasyOpc.ServerDescriptor")
ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"

Dim NodeDescriptor: Set NodeDescriptor =
CreateObject("OpcLabs.EasyOpc.DataAccess.DANodeDescriptor")
NodeDescriptor.ItemID = "Simulation.Random"

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
On Error Resume Next
Dim accessPaths: accessPaths = Client.BrowseAccessPaths(ServerDescriptor,
NodeDescriptor)
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0

Dim i: For i = LBound(accessPaths) To UBound(accessPaths)
    WScript.Echo "accessPaths(" & i & "): " & accessPaths(i)
Next
```

5.1.2.3.4 Browsing for OPC Classic Properties

Each OPC item has typically associated a set of OPC properties with it. OPC properties contain additional information related to the item. The OPC specifications define a set of common properties; however, each OPC server is free to implement some more, vendor-specific properties as well.

If you want to retrieve a list of all properties available on a given OPC item, call the BrowseProperties method, passing it the ItemID you are interested in. You will receive back a DAPropertyElementCollection object. Each DAPropertyElement contains information about one OPC property, such as its (numeric) PropertyId, data type, or a readable description. The PropertyId can be later used as an argument in calling methods such as GetPropertyValue.

You can use DAPropertyId.GetName and GetPropertyType methods to obtain the string identifier of the property, or its type. With OPC XML, properties are identified by a XML qualified name, and you will find it in the DAPropertyElement.QualifiedName property.

Constants for specific (well-known) OPC properties are contained in the DAPropertyIds enumeration.

Object Pascal

```
// This example shows how to enumerate all properties of an OPC item. For each
property, it displays its Id and description.

class procedure BrowseProperties.Main;
var
  Client: OpcLabs_EasyOpcClassic_TLB._EasyDAClient;
  Count: Cardinal;
  Element: OleVariant;
  ServerDescriptor: _ServerDescriptor;
  NodeDescriptor: _DANodeDescriptor;
  PropertyElement: _DAPropertyElement;
  PropertyElementEnumerator: IEnumVariant;
  PropertyElements: _DAPropertyElementCollection;
begin
  ServerDescriptor := CoServerDescriptor.Create;
  ServerDescriptor.ServerClass := 'OPCLabs.KitServer.2';

  NodeDescriptor := CoDANodeDescriptor.Create;
  NodeDescriptor.ItemId := 'Simulation.Random';

  // Instantiate the client object
  Client := CoEasyDAClient.Create;

  try
    PropertyElements := Client.BrowseProperties(
      ServerDescriptor,
      NodeDescriptor);
  except
    on E: EOleException do
    begin
      WriteLn(Format('*** Failure: %s', [E.GetBaseException.Message]));
      Exit;
    end;
  end;

  PropertyElementEnumerator := PropertyElements.GetEnumerator;
  while (PropertyElementEnumerator.Next(1, Element, Count) = S_OK) do
```

```
  begin
    PropertyElement := IUnknown(Element) as _DAPropertyElement;
    WriteLn('PropertyElements("', PropertyElement.PropertyId.NumericalValue,
'").Description: ', PropertyElement.Description);
  end;
end;
```

PHP

```
// This example shows how to enumerate all properties of an OPC item. For each
property, it displays its Id and description.

$ServerDescriptor = new COM("OpcLabs.EasyOpc.ServerDescriptor");
$ServerDescriptor->ServerClass = "OPCLabs.KitServer.2";

$NodeDescriptor = new COM("OpcLabs.EasyOpc.DataAccess.DANodeDescriptor");
$NodeDescriptor->ItemID = "Simulation.Random";

$Client = new COM("OpcLabs.EasyOpc.DataAccess.EasyDAClient");

try
{
    $PropertyElements = $Client->BrowseProperties($ServerDescriptor, $NodeDescriptor);
}
catch (com_exception $e)
{
    printf("*** Failure: %s\n", $e->getMessage());
    Exit();
}

foreach ($PropertyElements as $PropertyElement)
{
    printf("PropertyElements(\"%s\").Description: %s\n", $PropertyElement->PropertyID-
>NumericalValue, $PropertyElement->Description);
}
```

VBScript

```
Rem This example shows how to enumerate all properties of an OPC item. For each
property, it displays its Id and description.

Option Explicit

Dim ServerDescriptor: Set ServerDescriptor =
CreateObject("OpcLabs.EasyOpc.ServerDescriptor")
ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"

Dim NodeDescriptor: Set NodeDescriptor =
CreateObject("OpcLabs.EasyOpc.DataAccess.DANodeDescriptor")
NodeDescriptor.ItemID = "Simulation.Random"

Dim EasyDAClient: Set EasyDAClient =
CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
On Error Resume Next
Dim PropertyElements: Set PropertyElements =
EasyDAClient.BrowseProperties(ServerDescriptor, NodeDescriptor)
If Err.Number <> 0 Then
```

```
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0

Dim PropertyElement: For Each PropertyElement In PropertyElements
    WScript.Echo "PropertyElements(""" & PropertyElement.PropertyID.NumericalValue &
""").Description: " & PropertyElement.Description
Next
```

5.1.2.3.5 Discovering OPC UA Servers

OPC UA Discovery allows OPC Data Client to find available OPC UA servers, and determine how to make connections to them. There are several approaches to discovery, and they can be combined together to achieve the desired functionality. Clients and servers can be on the same host, on different hosts in the same subnet, or even on completely different locations in an administrative domain.

OPC Data Client provides following kinds of discovery:

In This Topic

- **OPC UA Local Discovery (Section 5.1.2.3.5.1)**. Obtains information about the servers on a specified host using OPC UA Local Discovery Server (LDS) running on that host.
- **OPC UA Network Discovery (Section 5.1.2.3.5.2)**. Also known as MulticastSubnet Discovery. The information is obtained from a Local Discovery Server with Multicast Extensions (LDS-ME), which uses the mDNS protocol to exchange the information about OPC UA servers with other LDS-ME-s on the network (or multiple networks).
- **OPC UA Global Discovery (Section 5.1.2.3.5.3)**. Obtains information about applications available in an administrative domain by interrogating an OPC UA Global Discovery Server (GDS).

It is also possible to access the discovery functionality in a common way, using **Generalized OPC UA Discovery (Section 5.1.2.3.5.4)**.

Flattened and unflattened results

By default, the results (the application element collection) of many of the methods described in this chapter are returned *flattened*. This means that a single OPC UA application may appear multiple times in the resulting collection, and each time it will have precisely one DiscoveryUriString associated with it.

Alternatively, you can use method overloads with the additional 'flat' argument, and set it true, in order to receive *unflattened* result. In this case, each OPC UA application will be contained just once in the resulting collection, but it may have one or more discovery URL in its DiscoveryUriStrings property. In this case, do not use the DiscoveryUriString property, because it will contain an empty string if the application has more than one discovery URL.

5.1.2.3.5.1 OPC UA Local Discovery

OPC Data Client-UA allows you to work with so called OPC-UA Local Discovery Server(s). OPC-UA Local Discovery Server is a special OPC-UA service that provides information about other OPC-UA servers available.

In This Topic

> ⚠ The term "local discovery" might be misleading sometimes. OPC UA Local Discovery is not just for discovering OPC UA servers that reside on the same computer as where your OPC UA client is. OPC UA Local Discover allows you to discover servers on a remote computer as well, provided that you know the host name of the computer, and the OPC UA Local Discovery Server is running on that remote computer.

If you want to retrieve a list of OPC Unified Architecture servers registered on a local or remote computer, call the DiscoverLocalServers method, passing it the name or address of the remote machine.

You will receive back a UADiscoveryElementCollection object, which is collection of UADiscoveryElement-s. Each element contains a server's discovery URL. The discovery URL is the main piece of information that you can further use if you want to connect to that OPC-UA server. Each UADiscoveryElement contains information gathered about one OPC server found by the discovery process, including things like the application name, application type, its Product URI etc.

C#

```
// This example shows how to obtain application URLs of all OPC Unified Architecture
servers on a given machine.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.Discovery;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    class DiscoverLocalServers
    {
        public static void Overload1()
        {
            // Instantiate the client object
            var client = new EasyUAClient();

            // Obtain collection of server elements
            UADiscoveryElementCollection discoveryElementCollection;
            try
            {
                discoveryElementCollection = client.DiscoverLocalServers("opcua.demo-
this.com");
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message);
                return;
            }

            // Display results
            foreach (UADiscoveryElement discoveryElement in discoveryElementCollection)
                Console.WriteLine("discoveryElementCollection[\"
{0}\"].ApplicationUriString: {1}",
                    discoveryElement.DiscoveryUriString,
```

```
discoveryElement.ApplicationUriString);

            // Example output:
            // discoveryElementCollection["opc.tcp://opcua.demo-
this.com:51210/UA/SampleServer"].ApplicationUriString: urn:Test-PC:UA Sample Server
            // discoveryElementCollection["http://opcua.demo-
this.com:51211/UA/SampleServer"].ApplicationUriString: urn:Test-PC:UA Sample Server
        }
    }
}
```

In .NET, if you want to connect to the discovered OPC server later in your code by calling other methods, use the built-in conversion of UADiscoveryElement to UAEndpointDescriptor, and pass the resulting object as an endpointDescriptor argument either directly to some other method call.

When performing a local discovery of OPC-UA servers, the component attempts to connect to multiple possible discovery endpoints in parallel, speeding up the discovery. This behavior is controlled by the ParallelDiscovery property in the UADiscoveryParameters object. The endpoints that the components attempts to use for discovery on a given host (either sequentially, or in parallel), are given by the DiscoveryUriTemplateStrings property of the UAHostParameters.

You can also bypass the use of UAHostParameters, and call the DiscoverLocalServers overload that takes an input array or URL strings to attempt discovery on.

There are also DiscoverLocalApplications methods, which allow you to specify the application types you are interested in, using the combination of flags from the UAApplicationTypes enumeration. This can be useful e.g. if you want to do hierarchical discovery and return also the discovery servers (which are not returned by default).

The FindLocalApplications method can be used, if you want to interrogate specific discovery endpoints.

        DiscoveryElement.ApplicationUriString
Next
```

Note that QuickOPC returns UADiscoveryElementCollection from all OPC UA discovery methods, but the amount of information contained in each returned UADiscoveryElement depends on the discovery approach used. For OPC UA Local Discovery, following primary properties of each UADiscoveryElement are filled in:

- ApplicationName
- ApplicationType
- ApplicationUriString
- DiscoveryProfileUriString
- DiscoveryUriString (see further down for more information)
- DiscoveryUriStrings (see further down for more information)
- GatewayServerUriString
- ProductUri

> ⚠ OPC UA Local Discovery Server (LDS) is not part of OPC Data Client installation.

5.1.2.3.5.2 OPC UA Network Discovery

OPC Data Client-UA allows you to obtain information about OPC UA servers from a Local Discovery Server with Multicast Extensions (LDS-ME), which uses the mDNS protocol to exchange the information about OPC UA servers with other LDS-ME-s on the network (or multiple networks).

In .NET, if you want to retrieve a list of OPC Unified Architecture servers available on your network, call the DiscoverNetworkServers method without further parameters. This will obtain the information about servers using the LDS-ME installed on the machine where the component is running, and without further restricting (filtering) them.

Further in .NET, if you want to retrieve a list of OPC Unified Architecture servers available on your network, call the DiscoverNetworkServers method with one or two arguments, passing it

- a StringCollection which specifies the server capabilities you are looking for,
- the name of the machine where the LDS-ME is running,
- or both.

In COM, the DiscoverNetworkServers method has two arguments, and therefore if you want no filtering, pass a null reference (or an empty collection) as the first argument, and pass "localhost" as the second argument if you want to use the LDS-ME installed on your machine.

In all cases described above, you will receive back a UADiscoveryElementCollection object, which is collection of UADiscoveryElement-s. Each element contains a server's discovery URL. The discovery URL is the main piece of information that you can further use if you want to connect to that OPC-UA server. Each UADiscoveryElement contains information gathered about one OPC server found by the discovery process, including things like the server name, application type, and - mainly - its DiscoveryUriString.

C#

```
// This example shows how to obtain information about OPC UA servers available on the
network.
// The result is flat, i.e. each discovery URL is returned in separate element, with
possible repetition of the servers.

using System;

            Next discoveryElement
        End Sub
    End Class
End Namespace
```

Note that QuickOPC returns UADiscoveryElementCollection from all OPC UA discovery methods, but the amount of information contained in each returned UADiscoveryElement depends on the discovery approach used. For OPC UA Global Discovery and OPC UA Network Discovery, only following primary properties of each UADiscoveryElement are filled in:

- ApplicationType
- DiscoveryUriString
- ServerCapabilities
- ServerName

⚠ OPC UA Local Discovery Server with Multicast Extensions (LDS-ME) is not part of OPC Data Client installation.

5.1.2.3.5.3 OPC UA Global Discovery

OPC Data Client-UA allows you to query information contained in so called OPC-UA Global Discovery Server(s). A Global Discovery Server (GDS) maintains discovery information for OPC UA applications available in an administrative domain.

If you want to retrieve a list of OPC Unified Architecture servers in an administrative domain, call the DiscoverGlobalServers method, passing it the endpoint of the GDS.

In addition, you can call an overload of the DiscoverGlobalServers method that also takes a filter parameter of

type UAQueryServerFilter. Using this filter, you can limit the search only to servers that meet the specified criteria. The criteria include:

- Application name.
- Application URI string.
- Product URI string.
- Server capabilities.

You can also call the EasyUAClient.DiscoverGlobalServers method that takes no arguments, in which case the endpoint descriptor of the GDS will be taken from the GdsEndpointDescriptor property of the InstanceParameters.

In all cases described above, you will receive back a UADiscoveryElementCollection object, which is collection of UADiscoveryElement-s. Each element contains a server's discovery URL. The discovery URL is the main piece of information that you can further use if you want to connect to that OPC-UA server. Each UADiscoveryElement contains information gathered about one OPC server found by the discovery process, including things like the application name, server capabilities, etc.

C#

```
// This example shows how to obtain information about OPC UA servers from the Global
Discovery Server (GDS).
// The result is flat, i.e. each discovery URL is returned in separate element, with
possible repetition of the servers.

using System;
using OpcLabs.EasyOpc.UA;

discoveryElement.ApplicationUriString)
                Console.WriteLine("Product URI string: {0}",
discoveryElement.ProductUriString)
            Next discoveryElement
        End Sub
    End Class
End Namespace
```

In .NET, if you want to connect to the discovered OPC server later in your code by calling other methods, use the built-in conversion of UADiscoveryElement to UAEndpointDescriptor, and pass the resulting object as an endpointDescriptor argument either directly to some other method call.

Note that QuickOPC returns UADiscoveryElementCollection from all OPC UA discovery methods, but the amount of information contained in each returned UADiscoveryElement depends on the discovery approach used. For OPC UA Global Discovery and OPC UA Network Discovery, only following primary properties of each UADiscoveryElement are filled in:

- ApplicationType
- DiscoveryUriString
- ServerCapabilities
- ServerName

> ⚠ OPC UA Global Discovery Server (GDS) is not part of OPC Data Client installation.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

5.1.2.3.5.4 Generalized OPC UA Discovery

The various kinds of OPC UA discovery can be generalized into just one method, Discover. This method is given a discovery query argument (of UADiscoveryQuery type) that tells it the requirements for the discovery. The specific kinds of OPC UA discovery described earlier are, in fact, implemented by constructing the discovery query appropriately, and then calling the Discover method.

The UADiscoveryQuery type is an abstract class which is at the root of a structured class hierarchy, with several concrete subclasses:

- UAGlobalApplicationDiscoveryQuery is for searching the applications globally in the administrative domain. With this query, you need to specify the GDS endpoint, and optionally a filter (UAQueryServerFilter), used to find servers that meet the specified criteria.
- UALocalApplicationDiscoveryQuery is used when you know the LDS endpoints, and want to perform discovery on these endpoints (usually in parallel). This is a specialized kind of local discovery.
- UALocalApplicationDiscoveryQuery is for finding applications local to a specified host.
- UANetworkServerDiscoveryQuery is for finding servers on a multicast subnet (or more connected subnets) using LDS-ME (Local Discovery Server with Multicast Extensions).

This generalized discovery mechanism allows for flexibility both on the component and developer sides, and possible future expansion with other kinds of discovery, without a need to introduce new methods into the IEasyUAClient interface.

5.1.2.3.6 Browsing for OPC UA Nodes

Principles

In This Topic

In OPC Unified Architecture, the address space is composed of nodes. The nodes are interconnected by means of references. The references do not necessarily have to be hierarchical; this means that the address space does not form a tree, but it is generally an interconnected “mesh” of nodes.

Nodes are of different node classes, and each node class has a fixed set of attributes, defined in the OPC specification. References can also be of various types, and the set of reference types is extensible.

OPC Data Client gives you methods to traverse through the address space information and obtain the information available there. It is also possible to filter the returned nodes by criteria such as the node classes of interest, or reference types to follow.

The address space may contain all kinds of information and various node classes and types of references. In this chapter, we will focus on browsing for node classes and reference types that are relevant for data access tasks.

There are following browse methods specialized for data access:

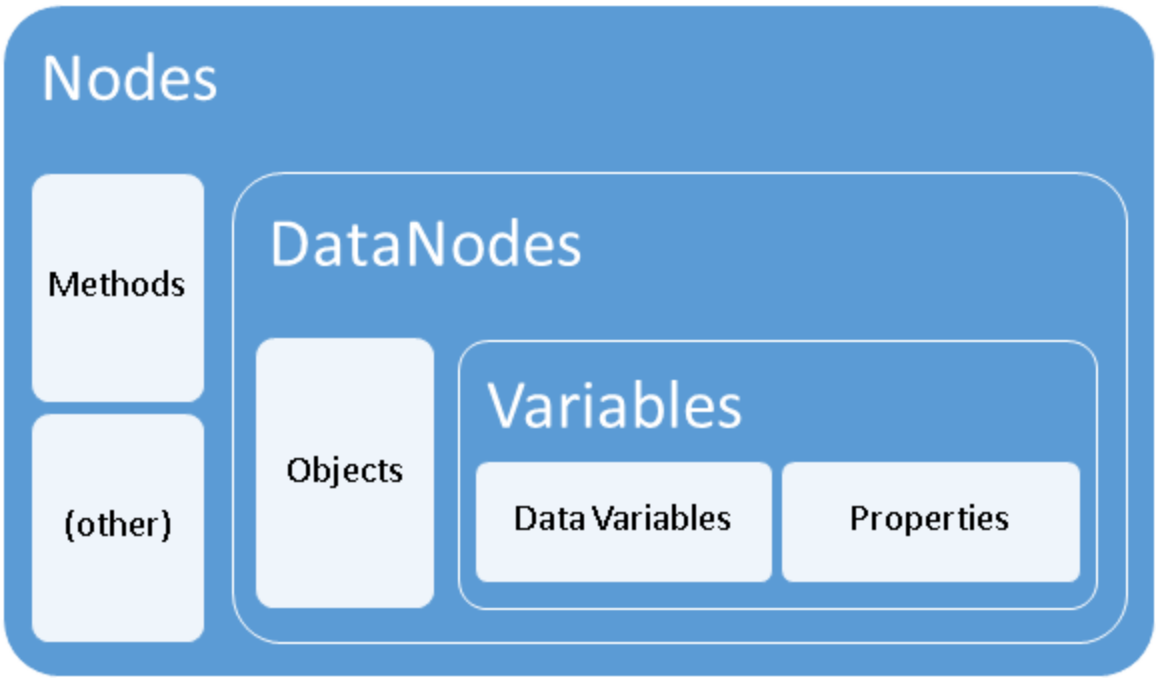
- BrowseObjects
- BrowseDataVariables
- BrowseProperties
- BrowseVariables
- BrowseDataNodes

Other browsing methods are:

- BrowseMethods
- Browse

Objects (returned by the BrowseObjects method) are equivalent of folders in a file system – they provide means of organizing other nodes logically. Data variables (returned by the BrowseDataVariables method) represent a value, and clients can read the value, write the value, or subscribe to changes of the value. Properties (returned by the BrowseProperties method) represent additional characteristics of a node which is not described by its attributes. Variables (either data variables, or properties), are returned by the BrowseVariables method. The BrowseDataNodes method returns all kinds of data nodes – and we use the term data nodes for any of objects, variables, or properties.

The following picture shows the relationship between various browsing options.



If you want to retrieve a list of all nodes that can be followed from a given node (or from an Objects folder that is a default starting point for data access browsing) of the OPC server, call one of the methods listed above. You will receive back a UANodeElementCollection, which is a collection of UANodeElement objects. Each UANodeElement contains information gathered about one node that can be followed from a given node, such as its browse name, its node ID, its display name, or a type definition. The UANodeElement is convertible to UANodeDescriptor, and you can therefore pass it to methods for further browsing from that node, or to methods like Read, ReadValue, SubscribeMonitoredItem, or SubscribeDataChange.

Note: In some cases, defined by the OPC UA specification, the elements returned in the UANodeElementCollection will have unique browse names. In general, however, OPC UA allows multiple returned elements share the same browse name.

The OPC UA address space may also contain Methods. They can be used to call (invoke) a code in the OPC UA server, passing input and output arguments to/from the method. Methods available on a specified object are returned by the BrowseMethods call.

The most generic address space browsing method is the Browse Method. It allows the widest range of filtering options by passing in an argument of type UABrowseParameters. You can specify any set of node classes, and reference type IDs, with this object.

Using the ReferenceTypeIds property in the UABrowseParameters, you can specify which references in the address space will be followed in browsing. The IncludeSubtypes flag determines whether subtypes of the specified reference type should be returned by the browsing.

Using the BrowseDirections property in the UABrowseParameters, you can specify which directions of the references the Browse method should return. The available choices are given by the UABrowseDirections enumeration, and are Forward, Inverse, and Both.

Examples

C#

```
// This example shows how to obtain "data nodes" (objects, variables and properties)
under the "Objects" node in the address
// space.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    class BrowseDataNodes
    {
        public static void Overload1()

5.1.2.4 Subscribing to Information (OPC Data)

If your application needs to monitor changes of certain process value (OPC Classic item, OPC UA monitored item), it can subscribe to it, and receive notifications when the value changes. For performance reasons, this approach is preferred over repeatedly reading the item's value (polling). Note that OPC Data Client has internal optimizations which greatly reduce the negative effects of polling, however subscription is still preferred.

OPC Data Client contains methods that allow you to subscribe to OPC Classic items or OPC UA monitored items, change the subscription parameters, and unsubscribe.

5.1.2.4.1 Subscribing to OPC Classic Items

Subscription is initiated by calling either SubscribeItem or SubscribeMultipleItems method. For any change in the subscribed item's value, your application will receive the ItemChanged event notification, described further below. Obviously, you first need to hook up event handler for that event, and in order to prevent event loss, you should do it before subscribing. Alternatively, you can pass a callback method into the SubscribeItem or SubscribeMultipleItems call.

Values of some items may be changing quite frequently, and receiving all changes that are generated is not desirable for performance reasons; there are also physical limitations to the event throughput in the system. Your application needs to specify the requested update rate, which effectively tells the OPC server that you do not need to receive event notifications any faster than that. For OPC items that support it, you can optionally specify a percent deadband; only changes that exceed the deadband will generate an event notification.

In OPC Data Client.NET, the requested update rate, percent deadband, and data type are all contained in a DAGroupParameters object.

A single item

If you want to subscribe to a specific OPC item, call the SubscribeItem method. You can pass in individual arguments for machine name, server class, ItemID, data type, requested update rate, and an optional percent deadband. Usually, you also pass in a State argument of type Object (in OPC Data Client.NET) or VARIANT (in OPC Data Client-COM). When the item's value changes, the State argument is then passed to the ItemChanged event handler in the EasyDAItemChangedEventArgs.Arguments.State property. The SubscribeItem method returns a subscription handle that you can later use to change the subscription parameters, or unsubscribe.

C#

```
// Hooking up events and receiving OPC item changes.

using System;
using System.Threading;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class SubscribeItem
    {
        public static void Main1()
        {
            using (var client = new EasyDAClient())
            {
                var eventHandler = new
EasyDAItemChangedEventHandler(client_ItemChanged);
                client.ItemChanged += eventHandler;

                Console.WriteLine("Subscribing item...");
                client.SubscribeItem("", "OPCLabs.KitServer.2", "Demo.Ramp", 200);
                Thread.Sleep(30 * 1000);
                client.UnsubscribeAllItems();
                client.ItemChanged -= eventHandler;
            }
        }
```

```
        static void client_ItemChanged(object sender, EasyDAItemChangedEventArgs e)
        {
            if (e.Succeeded)
                Console.WriteLine(e.Vtq);
            else
                Console.WriteLine("*** Failure: {0}", e.ErrorMessageBrief);
        }
    }
}
```

of the item with each change.
//
// Some related documentation: http://php.net/manual/en/function.com-event-sink.php .
Pay attention to the comment that says
// "Be careful how you use this feature; if you are doing something similar to the
example below, then it doesn't really make
// sense to run it in a web server context.". What they are trying to say is that
processing a web request should be
// a short-lived code, which does not fit well with the idea of being subscribed to
events and received them over longer time.
// It is possible to write such code, but it is only useful when processing the request
is allowed to take relatively long. Or,
// when you are using PHP from command-line, or otherwise - not to serve a web page
directly.
```

```
//
// Subscribing to QuickOPC-COM events in the context of PHP Web application, while not
imposing the limitations to the request
// processing time, has to be "worked around", e.g. using the "event pull" mechanism.

class DEasyDAClientEvents {
    function ItemChanged($varSender, $varE)
    {
        if ($varE->Succeeded)
        {
        print $varE->Vtq->ToString();
            print "\n";
        }
        else
        {
            printf("*** Failure: %s\n", $varE->ErrorMessageBrief);
        }
    }

    WScript.Echo "e.Vtq.Quality: " & e.Vtq.Quality
End Sub
```

In OPC Data Client.NET, you can also pass in a combination of ServerDescriptor, DAItemDescriptor and DAGroupParameters objects, in place of individual arguments.

The State argument is typically used to provide some sort of correlation between objects in your application, and the event notifications. For example, if you are programming an HMI application and you want the event handler to update the control that displays the item's value, you may want to set the State argument to the control object itself. When the event notification arrives, you simply update the control indicated by the State property of EasyDAItemChangedEventArgs, without having to look it up by ItemId or so.

Multiple items

To subscribe to multiple items simultaneously in an efficient manner, call the SubscribeMultipleItems method (instead of multiple SubscribeItem calls in a loop). You receive back an array of integers, which are the subscription handles.

You pass in an array of DAItemGroupArguments objects (each containing information for a single subscription to be made), to the SubscribeMultipleItems method.

C#

```
// This example shows how subscribe to changes of multiple items and display the value
of the item with each change.

using System;

```

Common considerations

Note: It is NOT an error to subscribe to the same item twice (or more times), even with precisely the same parameters. You will receive separate subscription handles, and with regard to your application, this situation will look no different from subscribing to different items. Internally, however, the subscription made to the OPC server will be optimized (merged together) if possible.

5.1.2.4.2 Subscribing to OPC UA Monitored Items

Subscription is initiated by calling one of the SubscribeMonitoredItem, SubscribeDataChange, or SubscribeMultipleMonitoredItems method. For any significant change in the subscribed item, your application will receive the DataChangeNotification event notification, described further below. Obviously, you first need to hook up event handler for that event, and in order to prevent event loss, you should do it before subscribing. Alternatively, you can pass a callback method into the SubscribeMonitoredItem, SubscribeDataChange or SubscribeMultipleMonitoredItems call.

In This Topic

Some items may be changing quite frequently, and receiving all changes that are generated is not desirable for performance reasons; there are also physical limitations to the event throughput in the system. You may also want to influence the amount of received information, or control how and how often the information is delivered. OPC Data Client-UA has two sets of parameters for this: subscription parameters and monitoring parameters.

Subscription parameters (can be fully contained in UASubscriptionParameters object) influence the information delivery. Main subscription parameters are the relative priority, and publishing interval (in milliseconds). The publishing interval defines the cyclic rate that the subscription is requested to return notifications to the client.

Monitoring parameters (can be fully contained in UAMonitoringParameters object) influence which information is delivered to the client. Main monitoring parameters are the data change filter (optional), size of monitored item queue, and sampling interval (in milliseconds; it is the fastest rate at which the monitored items should be accessed and evaluated).

The data change filter, if present, is contained in the UADataChangeFilter object, and defines the conditions under which a data change notification should be reported and, optionally, a deadband for value changes where no notification is generated. The Trigger property selects whether a notification is generated only when the status code associated with the value changes, or either the status code or the value change, or if any of the status code, value, or a source timestamp change. The DeadbandType property determines the type of deadband used, and can either select no deadband, absolute deadband, or percent deadband.

There are implicit conversions available from System.Double and UADataChangeTrigger to UADataChangeFilter. This allows the developer to simply use the absolute deadband, or the trigger selection, in place of any data change filter.

In order to make the settings of various parameters easier, OPC Data Client-UA allows you to omit the specification of publishing interval in subscription parameters by leaving it at zero (the default). In this case, the component will calculate the publishing interval by dividing the sampling interval by the so-called automatic publishing factor (EasyUAClient.SharedParameters.EngineParameters.AutomaticPublishingFactor) with a default pre-set by the component. The resulting value is limited by the value of EasyUAClient.SharedParameters.EngineParameters.FastestAutomaticPublishingInterval property. This algorithm should determine a suitable publishing interval in the most common cases.

A single node and attribute

If you want to subscribe to a specific value in OPC address space, call the SubscribeDataChange or SubscribeMonitoredItem method. These methods have number of overloads, but in its simplest form, only three arguments are necessary: an endpoint descriptor, node ID, and a sampling interval. Other callbacks allow you to specify e.g. the callback method, a user-defined state object, absolute deadband value, or pass in a full set of parameters using EasyUAMonitoredItemArguments object. The SubscribeDataChange and SubscribeMonitoredItem methods return a subscription handle that you can later use to change the subscription parameters, or unsubscribe.

It is common to pass in a State argument of type Object. When the monitored item's value changes, the State argument is then passed to the DataChangeNotification event handler (or your callback method) in the EasyUADataChangeNotificationEventArgs.Arguments object.

The State argument is typically used to provide some sort of correlation between objects in your application, and the event notifications. For example, if you are programming an HMI application and you want the event handler to update the control that displays the item's value, you may want to set the State argument to the control object itself. When the event notification arrives, you simply update the control indicated by the State property of EasyUADataChangeNotificationEventArgs.Arguments, without having to look it up by Node Id or so.

Multiple nodes or attributes

To subscribe to multiple items simultaneously in an efficient manner, call the SubscribeMultipleMonitoredItems method (instead of multiple SubscribeDataChange or SubscribeMonitoredItem calls in a loop). You receive back an array of subscription handles. You pass in an array of EasyUAMonitoredItemArguments objects (each containing information for a single subscription to be made), to the SubscribeMultipleMonitoredItems method.

C#

```
// This example shows how to subscribe to changes of multiple monitored items and
display the value of the monitored item with
// each change.

using System;

Common considerations

If you are only interested in certain kinds of changes in the monitored item, or need to reduce the amount of incoming notifications by specifying a deadband, use **OPC UA Data Change Filter (Section 5.1.2.4.2.1)**.

Note: It is NOT an error to subscribe to the same item twice (or more times), even with precisely same parameters. You will receive separate subscription handles, and with regard to your application, this situation will look no different from subscribing to different items. Internally, however, the subscription made to the OPC server might be optimized (merged together), depending on other parameters and circumstances.

5.1.2.4.2.1 OPC UA Data Change Filter

OPC UA Data Change Filter is used when you are only interested in certain kinds of changes in the monitored item, or need to reduce the amount of incoming notifications by specifying a deadband. The Data Change Filter defines the conditions under which a data change notification should be reported and, optionally, a range or band for value changes where no data change notification is generated.

The data change filter, in its entirety, is represented by the UADataChangeFilter Class, and is located in the DataChangeFilter Property of the UAMonitoringParameters Class. There are also useful overloads of various IEasyUAClient Interface extension methods, and implicit conversions, that allow you to shorten the code, if you do not want to create an instance of the data change filter class explicitly.

One of typical use cases for the data change filter is when the client application is only interested in receiving new data when the status code or the value has changed, but not when new data has been collected with the same value (and the new data only differ in the timestamp or timestamps). In such case, a data change filter with the trigger set to UADataChangeTrigger.StatusValue is used.

Following examples show this, for a single node and for multiple nodes.

C#

```
// This example shows how to subscribe to changes of a monitored item with data change
filter.
```

```
using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

5.1.2.4.3 Changing Existing Subscription (OPC Data)

It is not necessary to unsubscribe and then subscribe again if you want to change parameters of existing subscription, such as its update rate (OPC Classic) or sampling interval (OPC UA).

In This Topic

A single subscription

Instead of unsubscribing and subscribing again, change the parameters by calling the ChangeItemSubscription (OPC Classic) or ChangeDataChangeSubscription or ChangeMonitoredItemSubscription (OPC UA) method, passing it the subscription handle, and the new parameters in form of DAGroupParameters object (in OPC Data Client.NET), EasyUASubscriptionChangeArguments (in OPC Data Client-UA) or individually a requested update rate or sampling interval, and optionally a deadband value (this is the only way in OPC Data Client-COM).

Examples for OPC Classic:

C#

```
// This example shows how change the update rate of an existing subscription.

using System;
using System.Threading;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    partial class ChangeItemSubscription
    {
        public static void Main1()
        {
```

```
            using (var client = new EasyDAClient())
            {
                client.ItemChanged += client_ItemChanged;

5.1.2.4.4 Unsubscribing (OPC Data)

From a single item

In This Topic

If you no longer want to receive item change notifications, you need to unsubscribe from them. In OPC Data Client.NET (OPC Classic), to unsubscribe from a single OPC item, call the UnsubscribeItem method, passing it the subscription handle. In OPC Data Client-UA, to unsubscribe from a single monitored item, call the UnsubscribeMonitoredItem method, passing it the subscription handle as well.

Examples for OPC Classic:

C#

```
// This example shows how subscribe to changes of multiple items, and unsubscribe from
one of them.

using System;
using System.Threading;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    class UnsubscribeItem
    {
        public static void Main1()
        {
            using (var client = new EasyDAClient())
            {
                client.ItemChanged += client_ItemChanged;

                int[] handleArray = client.SubscribeMultipleItems(
                    new[] {
                            new DAItemGroupArguments("", "OPCLabs.KitServer.2",
"Simulation.Random", 1000, null),
                            new DAItemGroupArguments("", "OPCLabs.KitServer.2",
"Trends.Ramp (1 min)", 1000, null),
                            new DAItemGroupArguments("", "OPCLabs.KitServer.2",
"Trends.Sine (1 min)", 1000, null),
                            new DAItemGroupArguments("", "OPCLabs.KitServer.2",
"Simulation.Register_I4", 1000, null)
                        });

                Console.WriteLine("Processing item changed events for 30 seconds...");
                Thread.Sleep(30 * 1000);

                Console.WriteLine("Unsubscribing from the first item...");
                client.UnsubscribeItem(handleArray[0]);

                Console.WriteLine();

                Console.WriteLine("Processing item changed events for 30 seconds...");
                Thread.Sleep(30 * 1000);
            }
        }

        // Item changed event handler
        static void client_ItemChanged(object sender, EasyDAItemChangedEventArgs e)
        {
```

```
            if (e.Succeeded)
                Console.WriteLine("{0}: {1}", e.Arguments.ItemDescriptor.ItemId, e.Vtq);
            else
                Console.WriteLine("{0} *** Failure: {1}",
e.Arguments.ItemDescriptor.ItemId, e.ErrorMessageBrief);
        }
    }
}
```

From multiple items

In OPC Data Client.NET (OPC Classic), to unsubscribe from multiple OPC items in an efficient manner, call the UnsubscribeMultipleItems method (instead of calling UnsubscribeItem in a loop), passing it an array of subscription handles. In OPC Data Client-UA, to unsubscribe from multiple monitored items in an efficient manner, call the UnsubscribeMultipleMonitoredItems method (instead of calling UnsubscribeMonitoredItem in a loop), passing it an array of subscription handles.

Examples for OPC Classic:

VBScript

```
Rem This example shows how to unsubscribe from changes of multiple items.

Option Explicit

Dim ItemSubscriptionArguments1: Set ItemSubscriptionArguments1 =
CreateObject("OpcLabs.EasyOpc.DataAccess.OperationModel.EasyDAItemSubscriptionArguments")

ItemSubscriptionArguments1.ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"
ItemSubscriptionArguments1.ItemDescriptor.ItemID = "Simulation.Random"

From just some items

Obviously, when you are subscribing from multiple items, you can either choose to subscribe from the same set of items you used when subscribing (in which case you can simply pass the array of handles received from the SubscribeMultipleXXXX method to the UnsubscribeMultipleXXXX method), or, you can choose which items you unsubscribe from, picking just the handles you want.

Examples for OPC UA:

Object Pascal

```
// This example shows how to unsubscribe from changes of just some monitored
// items.

type
  TClientEventHandlers128 = class
    procedure OnDataChangeNotification(
      ASender: TObject;

```

From all items

In OPC Data Client Classic, you can also unsubscribe from all items you have previously subscribed to (on the same

instance of EasyDAClient object) by calling the UnsubscribeAllItems method. In OPC Data Client-UA, you can unsubscribe from all monitored items you have previously subscribed to (on the same instance of EasyUAClient object) by calling the UnsubscribeAllMonitoredItems method.

Examples for OPC Classic:

VBScript

```
Rem This example shows how to unsubscribe from changes of all items.

Option Explicit

Dim ItemSubscriptionArguments1: Set ItemSubscriptionArguments1 =
CreateObject("OpcLabs.EasyOpc.DataAccess.OperationModel.EasyDAItemSubscriptionArguments")

ItemSubscriptionArguments1.ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"
ItemSubscriptionArguments1.ItemDescriptor.ItemID = "Simulation.Random"
ItemSubscriptionArguments1.GroupParameters.RequestedUpdateRate = 1000

Dim ItemSubscriptionArguments2: Set ItemSubscriptionArguments2 =
CreateObject("OpcLabs.EasyOpc.DataAccess.OperationModel.EasyDAItemSubscriptionArguments")

ItemSubscriptionArguments2.ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"
ItemSubscriptionArguments2.ItemDescriptor.ItemID = "Trends.Ramp (1 min)"
ItemSubscriptionArguments2.GroupParameters.RequestedUpdateRate = 1000

Dim ItemSubscriptionArguments3: Set ItemSubscriptionArguments3 =
CreateObject("OpcLabs.EasyOpc.DataAccess.OperationModel.EasyDAItemSubscriptionArguments")

ItemSubscriptionArguments3.ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"
ItemSubscriptionArguments3.ItemDescriptor.ItemID = "Trends.Sine (1 min)"
ItemSubscriptionArguments3.GroupParameters.RequestedUpdateRate = 1000

Dim ItemSubscriptionArguments4: Set ItemSubscriptionArguments4 =
CreateObject("OpcLabs.EasyOpc.DataAccess.OperationModel.EasyDAItemSubscriptionArguments")

ItemSubscriptionArguments4.ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"
ItemSubscriptionArguments4.ItemDescriptor.ItemID = "Simulation.Register_I4"
ItemSubscriptionArguments4.GroupParameters.RequestedUpdateRate = 1000

Dim arguments(3)
Set arguments(0) = ItemSubscriptionArguments1
Set arguments(1) = ItemSubscriptionArguments2
Set arguments(2) = ItemSubscriptionArguments3
Set arguments(3) = ItemSubscriptionArguments4

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.DataAccess.EasyDAClient")
WScript.ConnectObject Client, "Client_"

WScript.Echo "Subscribing..."
Dim handleArray: handleArray = Client.SubscribeMultipleItems(arguments)

WScript.Echo "Waiting for 10 seconds..."
WScript.Sleep 10*1000

WScript.Echo "Unsubscribing..."
Client.UnsubscribeAllItems
```

```
WScript.Echo "Waiting for 10 seconds..."
WScript.Sleep 10*1000

Sub Client_ItemChanged(Sender, e)
    If Not (e.Succeeded) Then
        WScript.Echo "*** Failure: " & e.ErrorMessageBrief
        Exit Sub
    End If

    WScript.Echo e.Arguments.ItemDescriptor.ItemId & ": " & e.Vtq
End Sub
```

Examples for OPC UA:

C#

```
// This example shows how to unsubscribe from changes of all items.

Implicit and explicit unsubscribe

If you are no longer using the parent EasyDAClient or EasyUAClient object, you do not necessarily have to unsubscribe from the items, but it is highly recommended that you do so; if you don't, be aware of the possible consequences described below.

In OPC Data Client.NET and OPC Data Client-UA, the subscriptions will otherwise be internally alive until the .NET CLR (garbage collector) decides to finalize and destroy the parent EasyDAClient or EasyUAClient object (if ever); you cannot, however, determine that moment. You can alternatively call the Dispose method of the EasyDAClient (or EasyUAClient) object's IDisposable interface, which will unsubscribe from all items for you.

In OPC Data Client-COM, the subscriptions will otherwise be internally alive. You can alternatively release all references to the EasyDAClient object, which will unsubscribe from all items for you.

5.1.2.4.5 Obtaining Subscription Information (OPC Data)

If you need to obtain information about a subscription made or modified earlier, you have two methods available in OPC Data Client-UA.

Calling GetMonitoredItemArguments method with a handle obtained when the subscription was made will return an EasyUAMonitoredItemArguments object with all current parameters.

C#

```
// This example shows how to obtain parameters of certain monitored item subscription.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    class GetMonitoredItemArguments
    {
        public static void Main1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"
```

```
            // Instantiate the client object and hook events
            var client = new EasyUAClient();
            client.DataChangeNotification += client_DataChangeNotification;

            Console.WriteLine("Subscribing...");
            int[] handleArray = client.SubscribeMultipleMonitoredItems(new[]
                {
                    new EasyUAMonitoredItemArguments(null, endpointDescriptor,
                        "nsu=http://test.org/UA/Data/;i=10845", 1000),
                    new EasyUAMonitoredItemArguments(null, endpointDescriptor,
                        "nsu=http://test.org/UA/Data/;i=10853", 1000),
                    new EasyUAMonitoredItemArguments(null, endpointDescriptor,
                        "nsu=http://test.org/UA/Data/;i=10855", 1000)
                });

            Console.WriteLine("Getting monitored item arguments...");
            EasyUAMonitoredItemArguments monitoredItemArguments =

Calling GetMonitoredItemArgumentsDictionary obtains information about all monitored item subscriptions on the EasyUAClient object. It returns a dictionary of monitored item argument objects (as above). The dictionary is keyed by the monitored item subscription handles, and its values contain information describing each subscription.

C#

```
// This example shows how to obtain dictionary of parameters of all monitored item
subscriptions.

5.1.2.4.6 OPC Classic Item Changed Event or Callback

When there is a change in a value of an OPC item you have subscribed to, the EasyDAClient object generates an ItemChanged event. For subscription mechanism to be useful, you should hook one or more event handlers to this event.

To be more precise, the ItemChanged event is actually generated in other cases, too.

First of all, you always receive at least one ItemChanged event notification after you make a subscription; this notification either contains the initial data for the item, or an indication that data is not currently available. This behavior allows your application to rely on the component to provide at least some information for each subscribed item.

Secondly, the ItemChanged event is generated every time the component loses connection to the item, and when it reestablishes the connection. This way, your application is informed about any problems related to the item, and can process them accordingly if needed.

You will also receive the ItemChanged notification if the quality of the item changes (not just its actual data value).

The ItemChanged event notification contains an EasyDAItemChangedEventArgs argument. You will find all kind of relevant data in this object. Some properties in this object contain valid information no matter what kind of change the notification is about. These properties are inside the Arguments property.

For further processing, your code should always inspect the value of Exception property of the event arguments. If this property is set to a null reference, the notification carries an actual change in item's data, and the Vtq property has the new value, timestamp and quality of the item, in form of DAVtq object. If the Exception property is not a null reference, there has been an error related to the item, and the Vtq property is not valid. In such case, the Exception property contains information about the problem.

The ItemChanged event handler is called on a thread determined by the EasyDAClient component. For details, please refer to "Multithreading and Synchronization" chapter under "Advanced Topics".

In short, however, we can say that if you are writing e.g. Windows Forms application, the component takes care of calling the event handler on the user interface thread of the form, making it safe for your code to update controls on the form, or do other form-related actions, from the event handler.

5.1.2.4.7 OPC UA Monitored Item Changed Event or Callback

When there is a significant change related to monitored item you have subscribed to, the EasyUAClient object generates a DataChangeNotification event. What constitutes a significant change is given by the data change filter specified when the subscription was created. For subscription mechanism to be useful, you should hook one or more event handlers to this event.

To be more precise, the DataChangeNotification event is actually generated in other cases, too.

First of all, you always receive at least one DataChangeNotification event notification after you make a subscription; this notification either contains the initial data for the item, or an indication that data is not currently available. This behavior allows your application to rely on the component to provide at least some information for each subscribed item.

Secondly, the DataChangeNotification event is generated every time the component loses connection to the monitored item, and when it reestablishes the connection. This way, your application is informed about any problems related to the item, and can process them accordingly if needed.

You will also receive the DataChangeNotification notification if the status of the item changes (not just its actual data value). In fact, you can influence whether the timestamp or value changes trigger a notification, with the Trigger property in UADataChangeFilter.

The DataChangeNotification event notification contains an EasyUADataChangeNotificationEventArgs argument. You will

find all kind of relevant data in this object. Some properties in this object contain valid information no matter what kind of change the notification is about. These properties are in Arguments (containing also information such as SubscriptionParameters, MonitoringParameters, NodeDescriptor, EndpointDescriptor and State).

For further processing, your code should always inspect the value of Exception property of the event arguments. If this property is set to a null reference, the notification carries an actual change in item's data, and the AttributeData property has the new value, timestamps and status of the item, in form of UAAttributeData object. If the Exception property is not a null reference, there has been an error related to the item, and the AttributeData property is not valid. In such case, the Exception property contains information about the problem.

The DataChangeNotification event handler is called on a thread determined by the EasyUAClient component. For details, please refer to "Multithreading and Synchronization" chapter under "Advanced Topics".

In short, however, we can say that if you are writing e.g. Windows Forms application, the component takes care of calling the event handler on the user interface thread of the form, making it safe for your code to update controls on the form, or do other form-related actions, from the event handler.

5.1.2.4.8 Using Callback Methods Instead of Event Handlers (OPC Data)

Using event handlers for processing notifications is a standard way with many advantages. There also situations, however, where event handlers are not very practical. For example, if you want to do fundamentally different processing on different kinds of subscriptions, you end up with all notifications being processed by the same event handler, and you need to put in extra code to distinguish between different kinds of subscriptions they come from. Event handlers also require additional code to set up and tear down.

In This Topic

In order to overcome these problems, OPC Data Client components allow you to pass in a delegate for a callback method to subscription methods. There are subscription methods overloads that accept the callback method parameter. The callback method has the same signature (arguments) as the event handler, and is called by the component in addition to invoking the event handler (if you do not hook a handler to the event, only the callback method will be invoked). You can therefore pass in the delegate for the callback method right into the subscription method call, without setting up event handlers.

The callback method can also be specified using an anonymous delegate or a lambda expression, i.e. without having to declare the method explicitly elsewhere in your code. This is especially useful for short callback methods.

Examples for OPC Classic and XML-DA:

C#

```
// This example shows how subscribe to changes of a single item and display the value
of the item with each change,
// using a callback method specified using lambda expression.

using System;
using System.Diagnostics;
using System.Threading;
using OpcLabs.EasyOpc.DataAccess;
```

```
namespace DocExamples.DataAccess._EasyDAClient
{
    partial class SubscribeItem
    {
        public static void CallbackLambda()
        {
            // Instantiate the client object
            var client = new EasyDAClient();

            Console.WriteLine("Subscribing...");
            // The callback is a lambda expression the displays the value
            client.SubscribeItem("", "OPCLabs.KitServer.2", "Simulation.Random", 1000,
                (sender, eventArgs) =>
                {
                    Debug.Assert(eventArgs != null);

                    if (eventArgs.Succeeded)
                    {
                        Debug.Assert(eventArgs.Vtq != null);
                        Console.WriteLine(eventArgs.Vtq.ToString());
                    }
                    else

More...

For subscription methods that work with multiple subscriptions at once, there is also a Callback (in OPC Classic) or DataChangeCallback (in OPC-UA) property in the arguments objects that you can use for the same purpose.

Note that if you specify a non-null callback parameter to the subscription method, the callback method will be invoked in addition to the event handlers. If you use both event handlers and callback methods in the same application, and you do not want the event handlers to process the notifications that are also processed by the callback methods, you can either

- test the Callback (or DataChangeCallback) property in the event arguments of the event handler, and if it is not a null reference, the event has been processed by the callback method and you can ignore it, or
- use two instances of the EasyDAClient (or EasyAEClient or EasyUAClient) object, and set up event handlers on one instance and use the callback methods on the other instance.

5.1.2.5 Calling Methods in OPC-UA

In OPC-UA, Methods represent the function calls of Objects. Methods are called (invoked) and return after completion, whether successful or unsuccessful. Execution times for Methods may vary, depending on the function they are performing. A Method is always a component of an Object.

In This Topic

A single method

If you want to call a method on a specific object node in OPC UA, use the EasyUAClient.CallMethod method, passing it the endpoint descriptor, object node ID, method node ID, and optionally the method input arguments (if the method has any). The input arguments are specified by an array of objects. The number of arguments and their types must conform to the method's requirements.

If the operation is successful, it returns an array of output arguments of the method call. The number of output arguments and their types are given by the UA method.

C#

```
// This example shows how to call a single method, and pass arguments to and from it.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    class CallMethod
    {
        public static void Main1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            object[] inputs =
            {
                false,
                1,
                2,
                3,
                4,
                5,
```

```
                6,
                7,
                8,
                9,

Multiple methods; argument type conversion

For making multiple method calls (on the same or different object nodes) in an efficient manner, use the EasyUAClient.CallMultipleMethods method. You pass in an array of UACallArguments objects, each specifying the location of the object node, the method node, and the input arguments to be passed to the method.

If the originating tool or language cannot directly supply the argument in a type that is required for the method by the OPC UA server, you can have the value converted to the desired type internally by OPC Data Client. The corresponding type information can be passed in some method overrides, or inside a UACallArguments object (using the InputTypeCodes, InputTypeFullName or InputTypes property).

5.1.2.6 Setting Parameters (OPC Data)

While the most information needed to perform OPC tasks is contained in arguments to method calls, there are some component-wide parameters that are not worth repeating in every method call, and also some that have wider effect that influences more than just a single method call. You can obtain and modify these parameters through properties on the EasyDAClient or EasyUAClient object.

For the EasyDAClient object, following are its instance properties, i.e. if you have created multiple EasyDAClient objects, each will have its own copy of them:

- Mode: Specifies common parameters such as allowed and desired methods of accessing the data in the OPC server.
- HoldPeriods: Specifies optimization parameters that reduce the load on the OPC server.
- UpdateRates: Specifies the "hints" for OPC update rates used when other explicit information is missing.
- Timeouts: Specifies the maximum amount of time the various operations are allowed to take.

and

- SynchronizationContext: Contains synchronization context used by the object when performing event notifications.

C#

```
// This example shows how the OPC server can quickly be disconnected after writing a
value into one of its OPC items.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClientHoldPeriods
{
    class TopicWrite
    {
        public static void Main1()
        {
            var client = new EasyDAClient();
```

```
            client.InstanceParameters.HoldPeriods.TopicWrite = 100; // in milliseconds

            try
            {
                client.WriteItemValue("", "OPCLabs.KitServer.2",
"Simulation.Register_I4", 12345);
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
            }
        }
    }
}
```

VB.NET

```
' This example shows how the OPC server can quickly be disconnected after writing a
value into one of its OPC items.

Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess._EasyDAClientHoldPeriods
    Friend Class TopicWrite
        Public Shared Sub Main1()
            Dim client = New EasyDAClient()

            client.InstanceParameters.HoldPeriods.TopicWrite = 100 ' in milliseconds

            Try
                client.WriteItemValue("", "OPCLabs.KitServer.2",
"Simulation.Register_I4", 12345)
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message)
            End Try
        End Sub
    End Class
End Namespace
```

For the EasyUAClient object, following are its instance properties, i.e. if you have created multiple EasyUAClient objects, each will have its own copy of them:

- SynchronizationContext: Contains synchronization context used by the object when performing event notifications.

Instance properties can be modified from your code.

In OPC Data Client.NET and OPC Data Client-UA, if you have placed the EasyDAClient, EasyAEClient or EasyUAClient object on the designer surface, most instance properties can also be directly edited in the Properties window in Visual Studio.

In OPC Data Client-COM, your code can override the defaults if needed, by setting the properties accordingly.

Following properties are static, i.e. shared among all instances of EasyDAClient object:

- EngineParameters: Contains global parameters such as frequencies of internal tasks performed by the component.
- MachineParameters: Contains parameters related to operations that target a specific computer but not a specific OPC server, such as browsing for OPC servers using various methods.
- ClientParameters: Contains parameters that influence operations that target a specific OPC server a whole.
- TopicParameters: Contains parameters that influence operations that target a specific OPC item.

Following properties are static, i.e. shared among all instances of EasyUAClient object:

- EngineParameters: Contains global parameters such as frequencies of internal tasks performed by the component.

Following properties are static unless the EasyUAClient is configured as isolated:

- HostParameters: Contains parameters that influence the behavior of the component on the host level.
- DiscoveryParameters: Contains parameters that influence the behavior of the component for the discovery.
- MonitoredItemParameters: Contains parameters related to operations that target a specific monitored item (e.g. a retrial delay).
- SessionParameters: Contains parameters that influence operations that target an OPC-UA session, such as Endpoint Selection Policy, User Identity, and Keep Alive Interval.
- SubscriptionParameters: Contains parameters that influence operations that target an OPC-UA subscription (e.g. a retrial delay).

Please use the Reference documentation for details on meaning of various properties and their use.

Static properties can be modified from your code. If you want to modify any of the static properties, you must do it before the first instance of EasyDAClient , EasyAEClient or EasyUAObject object is created.

You can also use the following components to set the static properties:

Configuration Component	Sets Static Properties of
EasyAEClientConfiguration component - 	EasyAEClient class
EasyDAClientConfiguration component - 	EasyDAClient class
EasyUAClientConfiguration component - 	EasyUAClient class

In Visual Studio, drag the corresponding component from the Toolbox to the designer surface, select it, and you can then view and modify the settings in the Properties window.

Note that the EasyXXClientConfiguration (where **XX** is either **AE**/**DA**/**UA**) components are just a "peek" to properties of the EasyXXClient that are static in nature. For this reason, you should normally have just one instance of the EasyXXClientConfiguration component in your application, and you should place it in such a way that it gets instantiated before the first operations on the EasyXXClient object take place. You can achieve this easily e.g. by placing the EasyXXClientConfiguration component onto the main (first) form of your application.

The EasyUAClientConfiguration component also has a LogEntry event, which functions as a "projection" of the static EasyUAClient.LogEntry event. You can easily hook an event handler to this event to process log entries generated by the EasyUAClient component.

5.1.2.6.1 User Identity in QuickOPC-UA

OPC UA Servers may require that the user making a connection from the OPC UA client is authenticated, and reject the connection of the authentication fails. In addition, different users may have different permissions (authorization) for various operations on the OPC UA Server.

You can specify the identity of the user making the connection using the UserIdentity property. This property is a UserIdentity object that contains following user token infos:

- AnonymousTokenInfo: An anonymous user.
- UserNameTokenInfo: A user name token (with optional password).
- X509CertificateTokenInfo: A user token represented by an X.509 certificate.
- KerberosTokenInfo: A Kerberos (issued) user token.

Note: The Kerberos token info may represent an explicitly specified user identity (if you set KerberosTokenInfo.NetworkSecurity.CustomNetworkCredential to true and specify additional parameters, such as the user name, password, and domain), or it can represent the current user running the code (if KerberosTokenInfo.NetworkSecurity.CustomNetworkCredential is set to false).

Zero, one, or more user token infos (of different types) may be specified in the UserIdentity object. By default, no user token info is specified. The user token infos are always present (i.e. non-null), but they are only used if they are filled in with data. For example, if you leave the UserName and Password in the UserNameTokenInfo empty, the user name token will not be used. If you, however, start putting values into any of the token infos, you need to fill in everything necessary in that token, otherwise an error may occur. For an AnonymousTokenInfo, the anonymous token is used when its IsConfigured property is set to true.

You can easily create a UserIdentity with certain user token by one of the following static methods:

- UserIdentity.CreateAnonymousIdentity
- UserIdentity.CreateKerberosIdentity
- UserIdentity.CreateUserNameIdentity
- UserIdentity.CreateX509Certificate

When OPC Data Client-UA makes a connection to the OPC UA server, it selects the user token according to its built-in token selection policy. The OPC UA server is interrogated for user token policies available on the endpoint, and the OPC Data Client-UA selects the most appropriate one from them.

When you set the user identity in the above described way, i.e. in the session parameters object, it applies to all sessions (connections) made by that EasyUAClient object. In addition to this, it is also possible to specify the user identity directly for a specific connection, i.e. on the UAEndpointDescriptor object.

There is a UserIdentity property on the UAEndpointDescriptor as well, and the user token infos contained there are merged together with those coming from the session parameters, for each connection made on that endpoint. For details on easier handling user identities specified directly on an endpoint, see **OPC UA Server Endpoints (Section 4.11.1)**.

5.1.2.6.2 Server Diagnostics in OPC-UA

The DiagnosticsMasks property on the SessionParameters allows the developer to specify the types of vendor-specific diagnostics to be returned by the OPC-UA server in the responses. The information from the server responses is then made available in the Diagnostics collection of OperationResult and EasyDataChangeNotificationEventArgs objects.

5.1.3 Imperative Programming Model for OPC Classic A&E

This chapter gives you guidance in how to implement the common tasks that are needed when dealing with OPC Classic Alarms and Events server from the client side. You achieve these tasks by calling methods on the EasyAEClient object.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

5.1.3.1 Obtaining Information (OPC A&E)

Methods described in this chapter allow your application to obtain information from the underlying data source that the OPC Alarms and Events server connects to, or from the OPC server itself (getting condition state). It is assumed that your application already somehow knows how to identify the data it is interested in. If the location of the data is not known upfront, use methods described in Browsing for Information chapter first.

5.1.3.1.1 Getting Condition State (OPC A&E)

In OPC Alarms and Events, information is usually provided in form of event notifications, especially for transient (simple and tracking) events. For condition-related events, however, it is also possible to get (upon request) information about the current state of a specified condition.

If you want to obtain the current state information for the condition instance in an OPC Alarms and Events sever, call the GetConditionState method. You pass in individual arguments for machine name, server class, fully qualified source name, condition name, and optionally an array of event attributes to be returned. You will receive back an AEConditionState object holding the current state information about an OPC condition instance.

C#

```
// This example shows how to obtain current state information for the condition
instance corresponding to a Source and
// certain ConditionName.

using System;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class GetConditionState
    {
        public static void Main1()
        {
            var client = new EasyAEClient();
            AEConditionState conditionState;
```

```
            try
            {
                conditionState = client.GetConditionState("",
"OPCLabs.KitEventServer.2",
                    "Simulation.ConditionState1", "Simulated");
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }

            Console.WriteLine("ConditionState:");
            Console.WriteLine("    .ActiveSubcondition: {0}",
conditionState.ActiveSubcondition);
            Console.WriteLine("    .Enabled: {0}", conditionState.Enabled);
            Console.WriteLine("    .Active: {0}", conditionState.Active);
            Console.WriteLine("    .Acknowledged: {0}", conditionState.Acknowledged);
            Console.WriteLine("    .Quality: {0}", conditionState.Quality);
            // Remark: IAEConditionState has many more properties
        }
    }
}
```

VB.NET

```
' This example shows how to obtain current state information for the condition instance
corresponding to a Source and
' certain ConditionName.

Imports OpcLabs.EasyOpc.AlarmsAndEvents
Imports OpcLabs.EasyOpc.OperationModel

```

In OPC Data Client.NET, you can alternatively pass in a ServerDescriptor in place of machine name and server class arguments.

5.1.3.2 Modifying Information (OPC A&E)

Methods described in this chapter allow your application to modify information in the underlying data source that the OPC server connects to or in the OPC server itself (acknowledging conditions). It is assumed that your application already somehow knows how to identify the data it is interested in. If the location of the data is not known upfront, use methods

described Browsing for Information chapter first.

5.1.3.2.1 Acknowledging a Condition (OPC A&E)

If you want to acknowledge a condition in OPC Alarms and Events server, call the AcknowledgeCondition method. You pass in individual arguments for machine name, server class, fully qualified source name, condition name, and an active time and cookie corresponding to the transition of the condition you are acknowledging.

C#

```
// This example shows how to acknowledge an event condition in the OPC server.

using System;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.OperationModel;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class AcknowledgeCondition
    {
        static readonly EasyAEClient AEClient = new EasyAEClient();
        static readonly EasyDAClient DAClient = new EasyDAClient();

        static volatile bool _done;

        public static void Main1()
        {
            var eventHandler = new
EasyAENotificationEventHandler(AEClient_Notification);
            AEClient.Notification += eventHandler;

            Console.WriteLine("Processing event notifications for 1 minute...");
            var subscriptionFilter = new AESubscriptionFilter
            {
                Sources = new AENodeDescriptor[] { "Simulation.ConditionState1" }
            };
            int handle = AEClient.SubscribeEvents("", "OPCLabs.KitEventServer.2", 1000,
null, subscriptionFilter);

            // Give the refresh operation time to complete
            Thread.Sleep(5 * 1000);

            // Trigger an acknowledgeable event
            try
            {
                DAClient.WriteItemValue("", "OPCLabs.KitServer.2",
"SimulateEvents.ConditionState1.Activate", true);
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
```

```
opcException.GetBaseException().Message);
                return;
            }

            _done = false;
            DateTime endTime = DateTime.Now + new TimeSpan(0, 0, 5);

```

Optionally, you can pass in acknowledger ID (who is acknowledging the condition), and a comment string.

You can alternatively pass in a ServerDescriptor in place of machine name and server class arguments.

5.1.3.3 Browsing for Information (OPC A&E)

OPC Data Client contains methods that allow your application to retrieve and enumerate information about OPC Alarms and Events servers that exist on the network, and data available within these servers. Your code can then make use of the information obtained, e.g. to accommodate to configuration changes dynamically.

The methods we are describing here are for programmatic browsing, with no user interface (or when the user interface is provided by our own code).

5.1.3.3.1 Browsing for OPC A&E Servers

If you want to retrieve a list of OPC Alarms and Events servers registered on a local or remote computer, call the BrowseServers method, passing it the name or address of the remote machine (use empty string for local computer).

You will receive back a ServerElementCollection object. If you want to connect to this OPC server later in your code by calling other methods, use the built-in conversion of ServerElement to String, and pass the resulting string as a serverClass argument either directly to the method call, or to a constructor of ServerDescriptor object.

Each ServerElement contains information gathered about one OPC server found on the specified machine, including things like the server's CLSID, ProgID, vendor name, and readable description.

C#

```
// This example shows how to obtain all ProgIDs of all OPC Alarms and Events servers on
the local machine.

using System;
using System.Diagnostics;
using OpcLabs.EasyOpc;
using OpcLabs.EasyOpc.AlarmsAndEvents;

ServerElement.ProgId
Next
```

5.1.3.3.2 Browsing for OPC A&E Nodes (Areas and Sources)

Information in an OPC Alarms and Events server is organized in a tree hierarchy (process space), where the branch nodes (*event areas*) serve organizational purposes (similar to folders in a file system), while the leaf nodes actually generate events (similar to files in a file system) – they are called *event sources*. Each node has a "short" name that is unique among other branches or leaves under the same parent branch (or a root). Event sources can be fully identified using a "fully qualified" source name, which determines the OPC event source without a need to further qualify it with its position in the tree. OPC event source may look a process tag (e.g. "FIC101", or "Device1.Block101"), or possibly a device or subsystem identification; their syntax and meaning is fully determined by the particular OPC server they are coming from.

OPC Data Client gives you methods to traverse through the address space information and obtain the information available there. It is also possible to filter the returned nodes by a server specific filter string.

If you want to retrieve a list of all event areas under a given parent area (or under a root) of the OPC server, call the BrowseAreas method. You will receive an AENodeElementCollection object. Each AENodeElement contains information gathered about one sub-area node, such as its name, or an indication whether it has children.

C#

```
// This example shows how to obtain all areas directly under the root (denoted by empty
string for the parent).

using System;
using System.Diagnostics;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.AddressSpace;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class BrowseAreas
    {
        public static void Main1()
        {
            var client = new EasyAEClient();
            AENodeElementCollection nodeElements;
            try
            {
                nodeElements = client.BrowseAreas("", "OPCLabs.KitEventServer.2", "");
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }

            foreach (AENodeElement nodeElement in nodeElements)
            {
                Debug.Assert(nodeElement != null);

                Console.WriteLine("nodeElements[\"{0}\"]:", nodeElement.Name);
                Console.WriteLine("    .QualifiedName: {0}",
nodeElement.QualifiedName);
            }
        }
    }
}

                Debug.Assert(nodeElement IsNot Nothing)

                Console.WriteLine("nodeElements[""{0}""]:", nodeElement.Name)
                Console.WriteLine("    .QualifiedName: {0}", nodeElement.QualifiedName)
            Next nodeElement
        End Sub
    End Class

End Namespace
```

VBScript

```
Rem This example shows how to obtain all areas directly under the root (denoted by
empty string for the parent).

Option Explicit

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.AlarmsAndEvents.EasyAEClient")
On Error Resume Next
Dim NodeElements: Set NodeElements = Client.BrowseAreas("", "OPCLabs.KitEventServer.2",
"")
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0

Dim NodeElement: For Each NodeElement In NodeElements
    WScript.Echo "NodeElements(""" & NodeElement.Name & """):"
    With NodeElement
        WScript.Echo Space(4) & ".QualifiedName: " & .QualifiedName
    End With
Next
```

Similarly, if you want to retrieve a list of event sources under a given parent area (or under a root) of the OPC server, call the BrowseSources method. You will also receive back an AENodeElementCollection object, this time containing the event sources only. You can find information such as the fully qualified source name from the AENodeElement of any event source, extract it and pass it further to methods like GetConditionState or SubscribeEvents.

C#

```
// This example shows how to obtain all sources under the "Simulation" area.

using System;
using System.Diagnostics;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.AddressSpace;

Next
```

OPC Data Client.NET: The most generic address space browsing method is BrowseNodes. It combines the functionality of BrowseAreas and BrowseSources, and it also allows the widest range of filtering options by passing in an argument of type AEBrowseParameters.

5.1.3.3.3 Querying for OPC A&E Event Categories

Each OPC Alarms and Events server supports a set of specific event categories. The OPC specifications define a set of

recommended categories; however, each OPC server is free to implement some more, vendor-specific event categories as well.

If you want to retrieve a list of all categories available in a given OPC server, call the QueryEventCategories method. You will receive back an AECategoryElementCollection object.

C#

```
// This example shows how to enumerate all event categories provided by the OPC server.
For each category, it displays its Id
// and description.

using System;
using System.Diagnostics;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.AddressSpace;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class QueryEventCategories
    {
        public static void Main1()
        {
            var client = new EasyAEClient();
            AECategoryElementCollection categoryElements;
            try
            {
                categoryElements = client.QueryEventCategories("",
"OPCLabs.KitEventServer.2");
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }

            foreach (AECategoryElement categoryElement in categoryElements)
            {
                Debug.Assert(categoryElement != null);
                Console.WriteLine("CategoryElements[\"{0}\"].Description: {1}",
categoryElement.CategoryId, categoryElement.Description);
            }
        }
    }
}
```

VB.NET

```
' This example shows how to enumerate all event categories provided by the OPC server.
For each category, it displays its Id
' and description.

Imports OpcLabs.EasyOpc.AlarmsAndEvents
Imports OpcLabs.EasyOpc.AlarmsAndEvents.AddressSpace
```

```
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.AlarmsAndEvents._EasyAEClient

    Friend Class QueryEventCategories
        Public Shared Sub Main1()
            Dim client = New EasyAEClient()

            Dim categoryElements As AECategoryElementCollection
            Try
                categoryElements = client.QueryEventCategories("",
"OPCLabs.KitEventServer.2")
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message)
                Exit Sub
            End Try

            For Each categoryElement As AECategoryElement In categoryElements
                Debug.Assert(categoryElement IsNot Nothing)
                Console.WriteLine("CategoryElements[""{0}""].Description: {1}",
categoryElement.CategoryId, categoryElement.Description)
            Next categoryElement
        End Sub
    End Class

End Namespace
```

VBScript

```
Rem This example shows how to enumerate all event categories provided by the OPC
server. For each category, it displays its Id
Rem and description.

Option Explicit

Const AEEventTypes_All = 7

Dim ServerDescriptor: Set ServerDescriptor =
CreateObject("OpcLabs.EasyOpc.ServerDescriptor")
ServerDescriptor.ServerClass = "OPCLabs.KitEventServer.2"

Dim Client: Set Client = CreateObject("OpcLabs.EasyOpc.AlarmsAndEvents.EasyAEClient")
On Error Resume Next
Dim CategoryElements: Set CategoryElements =
Client.QueryEventCategories(ServerDescriptor, AEEventTypes_All)
If Err.Number <> 0 Then
    WScript.Echo "*** Failure: " & Err.Source & ": " & Err.Description
    WScript.Quit
End If
On Error Goto 0

Dim CategoryElement: For Each CategoryElement In CategoryElements
    WScript.Echo "CategoryElements(" & CategoryElement.CategoryId & ").Description: " &
CategoryElement.Description
Next
```

Each AECategoryElement contains information about one OPC event category, such as its (numeric) CategoryId, readable description, and associated event conditions and attributes. The CategoryId can be later used when creating an event filter, and is provided to you in event notifications.

C#

```

5.1.3.3.6 Querying for OPC A&E Event Attributes

The EasyAEClient.QueryCategoryAttributes method finds out event attributes that the server can provide as part of an event notification within a given event category.

5.1.3.4 Subscribing to Information (OPC A&E)

If your application needs to be informed about events occurring in the process and provided by the OPC Alarms and Events server, it can subscribe to them, and receive notifications.

OPC Data Client contains methods that allow you to subscribe to OPC events, change the subscription parameters, and unsubscribe.

5.1.3.4.1 Subscribing to OPC A&E Events

Subscription is initiated by calling the SubscribeEvents method. The component will call handlers for Notification event for each event that satisfies the filter criteria of the created subscription. Obviously, you first need to hook up event handler for that event, and in order to prevent event loss, you should do it before subscribing.

Events may be generated quite rapidly. Your application needs to specify the *notification rate*, which effectively tells the OPC Alarms and Events server that you do not need to receive event notifications any faster than that.

If you want to subscribe to particular set of OPC Events, call the SubscribeEvents method. You can pass in individual arguments for machine name, server class, and notification rate.

C#

```
// This example shows how to subscribe to events and display the event message with
each notification. It also shows how to
// unsubscribe afterwards.

using System;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient

    End If

    If Not e.EventData Is Nothing Then WScript.Echo e.EventData.Message
End Sub
```

Optionally, you can specify a subscription filter; it is a separate object of AESubscriptionFilterType type. Other optional parameters are attributes that should be returned in event notifications (separate set of attributes for each event category is needed), and the "active" and "refresh when active" flags. You can also pass in a State argument of any type. When any event notification is generated, the State argument is then passed to the Notification event handler in the EasyAENotificationEventArgs.Arguments.State object.

You can alternatively pass in a ServerDescriptor in place of machine name and server class arguments. You can also replace the individual notification rate, subscription filter, and returned attributes arguments by passing in an AESubscriptionParameters object.

The State argument is typically used to provide some sort of correlation between objects in your application, and the event notifications. For example, if you are programming an HMI application and you want the event handler to update the control that displays the event messages, you may want to set the State argument to the control object itself. When the event notification arrives, you simply update the control indicated by the State property of EasyAENotificationEventArgs, without having to look it up.

The "refresh when active" flag enables a functionality that is useful if you want to keep a "copy" of condition states (that primarily exist in the OPC server) in your application. When this flag is set, the component will automatically perform a subscription Refresh (see further below) after the connection is first time established, and also each time it is reestablished (after a connection loss). This way, the component assures that your code will get notifications that allow you to "reconstruct" the state of event conditions at any given moment.

Note: It is NOT an error to subscribe to the same set of events twice (or more times), even with precisely the same parameters. You will receive separate subscription handles, and with regard to your application, this situation will look no different from subscribing to different set of events.

5.1.3.4.2 Specifying event filters (OPC A&E)

Examples:

Filtering by category or categories:

C#

```
// This example shows how to filter the events by their category.

using System;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.OperationModel;
using OpcLabs.EasyOpc.DataAccess;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    partial class SubscribeEvents
    {
        static readonly EasyAEClient AEClient = new EasyAEClient();
        static readonly EasyDAClient DAClient = new EasyDAClient();

        public static void FilterByCategories()
        {
            var eventHandler = new
EasyAENotificationEventHandler(AEClient_Notification_FilterByCategories);
            AEClient.Notification += eventHandler;

            Console.WriteLine("Processing event notifications...");
            var subscriptionFilter = new AESubscriptionFilter
            {
                Categories = new long[] { 15531778 }
            };
            // You can also filter using event types, severity, areas, and sources.
            int handle = AEClient.SubscribeEvents("", "OPCLabs.KitEventServer.2", 1000,
null, subscriptionFilter);
```

```
            // Allow time for initial refresh
            Thread.Sleep(5 * 1000);

            // Set some events to active state.
            DAClient.WriteItemValue("", "OPCLabs.KitServer.2",
"SimulateEvents.ConditionState1.Activate", true);
            DAClient.WriteItemValue("", "OPCLabs.KitServer.2",
"SimulateEvents.ConditionState2.Activate", true);

            Thread.Sleep(10 * 1000);

            AEClient.UnsubscribeEvents(handle);
        }

        // Notification event handler
        static void AEClient_Notification_FilterByCategories(object sender,
EasyAENotificationEventArgs e)
        {
            Console.WriteLine();
            Console.WriteLine(e);
            if (!e.Succeeded)
                return;

            Console.WriteLine("Refresh: {0}", e.Refresh);
            Console.WriteLine("RefreshComplete: {0}", e.RefreshComplete);
            AEEventData eventData = e.EventData;
            if (eventData != null)
            {
                Console.WriteLine("Event.CategoryId: {0}", eventData.CategoryId);
                Console.WriteLine("Event.QualifiedSourceName: {0}",
eventData.QualifiedSourceName);
                Console.WriteLine("Event.Message: {0}", eventData.Message);
                Console.WriteLine("Event.Active: {0}", eventData.Active);
                Console.WriteLine("Event.Acknowledged: {0}", eventData.Acknowledged);
            }
        }
    }
}
```

5.1.3.4.3 Changing Existing Subscription (OPC A&E)

It is not necessary to unsubscribe and then subscribe again if you want to change parameters of existing subscription (such as its notification rate). Instead, change the parameters by calling the ChangeEventSubscription method, passing it the subscription handle, and the new parameters (notification rate, and optionally a filter and an "active" flag).

C#

```
// This example shows how to subscribe to events display the event message with each
notification. It also shows how to
// unsubscribe afterwards.

using System;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class ChangeEventSubscription
    {
        public static void Main1()
        {
            using (var client = new EasyAEClient())
            {
                var eventHandler = new
EasyAENotificationEventHandler(client_Notification);
                client.Notification += eventHandler;

                Console.WriteLine("Subscribing...");
                int handle = client.SubscribeEvents("", "OPCLabs.KitEventServer.2",
500);

                Console.WriteLine("Waiting for 10 seconds...");
                Thread.Sleep(10 * 1000);
```

```
                Console.WriteLine("Changing subscription...");
                client.ChangeEventSubscription(handle, 5 * 1000);

                Console.WriteLine("Waiting for 50 seconds...");
                Thread.Sleep(50 * 1000);

                client.UnsubscribeEvents(handle);
            }
        }

        // Notification event handler
        static void client_Notification(object sender, EasyAENotificationEventArgs e)
        {
            if (!e.Succeeded)
            {
                Console.WriteLine("*** Failure: {0}", e.ErrorMessageBrief);
                return;
            }

5.1.3.4.4 Unsubscribing from OPC A&E Events

A single subscription

In This Topic

If you no longer want to receive event notifications, you need to unsubscribe from them. To unsubscribe from events that you have previously subscribed to, call the UnsubscribeEvents method, passing it the subscription handle.

C#

```
// This example shows how to unsubscribe from specific event notifications.

using System;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class UnsubscribeEvents
    {
        public static void Main1()
        {
            using (var client = new EasyAEClient())
            {
                var eventHandler = new
EasyAENotificationEventHandler(client_Notification);
                client.Notification += eventHandler;

                Console.WriteLine("Subscribing...");
                int handle = client.SubscribeEvents("", "OPCLabs.KitEventServer.2",
1000);

                Console.WriteLine("Waiting for 10 seconds...");
                Thread.Sleep(10 * 1000);

                Console.WriteLine("Unsubscribing...");
                client.UnsubscribeEvents(handle);

                Console.WriteLine("Waiting for 10 seconds...");
                Thread.Sleep(10 * 1000);
            }
        }

        // Notification event handler
```

```
        static void client_Notification(object sender, EasyAENotificationEventArgs e)
        {
            if (!e.Succeeded)
            {
                Console.WriteLine("*** Failure: {0}", e.ErrorMessageBrief);
                return;
            }
            if (e.EventData != null)
                Console.WriteLine(e.EventData.Message);
        }
    }
}
```

VB.NET

```
' This example shows how to unsubscribe from specific event notifications.

Imports System.Threading

```

All subscriptions

You can also unsubscribe from all events you have previously subscribed to (on the same instance of EasyAEClient object) by calling the UnsubscribeAllEvents method.

C#

```
// This example shows how to unsubscribe from all event notifications.
```

```
using System;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class UnsubscribeAllEvents
    {
        public static void Main1()
        {
            using (var client = new EasyAEClient())
            {
                var eventHandler = new
EasyAENotificationEventHandler(client_Notification);
                client.Notification += eventHandler;

                Console.WriteLine("Subscribing...");
                client.SubscribeEvents("", "OPCLabs.KitEventServer.2", 1000);

                Console.WriteLine("Waiting for 10 seconds...");
                Thread.Sleep(10 * 1000);

                Console.WriteLine("Unsubscribing...");
                client.UnsubscribeAllEvents();

                Console.WriteLine("Waiting for 10 seconds...");
                Thread.Sleep(10 * 1000);
            }
        }

        // Notification event handler
        static void client_Notification(object sender, EasyAENotificationEventArgs e)
        {
            if (!e.Succeeded)
            {
                Console.WriteLine("*** Failure: {0}", e.ErrorMessageBrief);
                return;
            }
            if (e.EventData != null)
                Console.WriteLine(e.EventData.Message);
        }
    }
}
```

WScript.Echo "Waiting for 10 seconds..."
WScript.Sleep 10*1000

WScript.Echo "Unsubscribing..."
Client.UnsubscribeAllEvents
```

```
WScript.Echo "Waiting for 10 seconds..."
WScript.Sleep 10*1000

Rem Notification event handler
Sub Client_Notification(Sender, e)
    If Not (e.Succeeded) Then
        WScript.Echo "*** Failure: " & e.ErrorMessageBrief
        Exit Sub
    End If

    If Not e.EventData Is Nothing Then WScript.Echo e.EventData.Message
End Sub
```

If you are no longer using the parent EasyAEClient object, you should unsubscribe from the events, or dispose of the EasyAEClient object, which will do the same for you. Otherwise, the subscriptions will internally be still alive, and may cause problems related to COM reference counting.

5.1.3.4.5 Refreshing Condition States (OPC A&E)

Your application can obtain the current state of all conditions which are active, or which are inactive but unacknowledged, by requesting a "refresh" from an event subscription. The component will respond by sending the appropriate event notifications to the application, via the event handlers, for all conditions selected by the event subscription filter. When invoking the event handler, the component will indicate whether the invocation is for a refresh or is an original notification. Refresh and original event notifications will not be mixed in the same event notifications.

If you want to force a refresh, call the RefreshEventSubscription method, passing it the subscription handle.

C#

```
// This example shows how to for a refresh for all active conditions and inactive,
unacknowledged conditions.

using System;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;
using OpcLabs.EasyOpc.AlarmsAndEvents.OperationModel;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    class RefreshEventSubscription
    {
        static readonly EasyAEClient AEClient = new EasyAEClient();
        static readonly EasyDAClient DAClient = new EasyDAClient();

        public static void Main1()
        {
            var eventHandler = new
```

```
EasyAENotificationEventHandler(AEClient_Notification);
            AEClient.Notification += eventHandler;

            Console.WriteLine("Processing event notifications...");
            var subscriptionFilter = new AESubscriptionFilter
            {
                Sources = new AENodeDescriptor[] { "Simulation.ConditionState1",
"Simulation.ConditionState2", "Simulation.ConditionState3" }
            };
            int handle = AEClient.SubscribeEvents("", "OPCLabs.KitEventServer.2", 1000,
null, subscriptionFilter);

            // The component will perform auto-refresh at this point, give it time to
happen
            Console.WriteLine("Waiting for 10 seconds...");
            Thread.Sleep(10 * 1000);

            // Set some events to active state, which will cause them to appear in
refresh
            Console.WriteLine("Activating conditions and waiting for 10 seconds...");

5.1.3.4.6 OPC A&E Notification Event

When an OPC Alarms and Events server generates an event, the EasyAEClient object generates a Notification event. For subscription mechanism to be useful, you should hook one or more event handlers to this event.

To be more precise, the Notification event is actually generated in other cases, too - if there is any significant occurrence related to the event subscription. This can be for three reasons:

1. You receive the Notification when a successful connection (or re-connection) is made. In this case, the Exception and EventData properties of the event arguments are null references.
2. You receive the Notification when there is a problem with the event subscription, and it is disconnected. In this case, the Exception property contains information about the error. The EventData property is a null reference.
3. You receive one additional Notification after the component has sent you all notifications for the forced "refresh". In this case, the RefreshComplete property of the event arguments is set to 'true', and the Exception and EventData properties contain null references.

The notification for the Notification event contains an EasyAENotificationEventArgs argument. You will find all kind of relevant data in this object. Some properties in this object contain valid information under all circumstances. These properties are e.g. Arguments (including Arguments.State). Other properties, such as EventData, contain null references when there is no associated information for them. When the EventData property is not a null reference, it contains an AEEventData object describing the detail of the actual OPC event received from the OPC Alarms and Events server.

Before further processing, your code should always inspect the value of Exception property of the event arguments. If this property is not a null reference, there has been an error related to the event subscription, the Exception property contains information about the problem, and the EventData property does not contain a valid object.

If the Exception property is a null reference, the notification may be informing you about the fact that a "forced" refresh is complete (in this case, the RefreshComplete property is 'true'), or that an event subscription has been successfully connected or re-connected (in this case, the EventData property is a null reference). If none of the previous applies, the EventData property contains a valid AEEventData object with details about the actual OPC event generated by the OPC server.

Pseudo-code for the full **Notification** event handler may look similar to this:

> **if** notificationEventArgs.Exception is not null **then**
>
> *An error occurred and the subscription is disconnected, handle it (or ignore)*
>
> **else if** notificationEventArgs.RefreshComplete **then**
>
> *A "refresh" is complete; handle it (only needed if you are invoking a refresh explicitly)*
>
> **else if** notificationEventArgs.EventData is null **then**
>
> *Subscription has been successfully connected or re-connected, handle it (or ignore)*
>
> **else**
>
> *Handle the OPC event, details are in notificationEventArgs.EventData. You may use notificationEventArgs.Refresh flag for distinguishing refreshes from original notifications.*

The Notification event handler is called on a thread determined by the EasyAEClient component. For details, please refer to "Multithreading and Synchronization" chapter under "Advanced Topics".

5.1.3.4.7 Using Callback Methods Instead of Event Handlers (OPC A&E)

The subscription methods also allow you to directly specify the callback method (delegate) to be invoked for each event notification you are subscribing to.

For detailed discussion on this subject, please refer to “Using Callback Methods Instead of Event Handlers” under the “OPC Data Access Tasks” chapter. All information presented there applies to OPC Alarms and Events as well.

C#

```
// This example shows how to subscribe to events and display the event message with
each notification, using a callback method
// specified using lambda expression.

using System;
using System.Diagnostics;
using System.Threading;
using OpcLabs.EasyOpc.AlarmsAndEvents;

namespace DocExamples.AlarmsAndEvents._EasyAEClient
{
    partial class SubscribeEvents
    {
        public static void CallbackLambda()
        {
            // Instantiate the client object
            var client = new EasyAEClient();

            Console.WriteLine("Subscribing...");
            // The callback is a lambda expression the displays the event message
            client.SubscribeEvents("", "OPCLabs.KitEventServer.2", 1000,
                (sender, eventArgs) =>
                {
                    Debug.Assert(eventArgs != null);
                    if (!eventArgs.Succeeded)
                    {
                        Console.WriteLine("*** Failure: {0}",
eventArgs.ErrorMessageBrief);
                        return;
                    }
                    if (eventArgs.EventData != null)
                        Console.WriteLine(eventArgs.EventData.Message);
                });

            Console.WriteLine("Processing event notifications for 20 seconds...");
            Thread.Sleep(20 * 1000);

            Console.WriteLine("Unsubscribing...");
            client.UnsubscribeAllEvents();

            Console.WriteLine("Waiting for 2 seconds...");
            Thread.Sleep(2 * 1000);
        }
    }
}
```

VB.NET

```
' This example shows how to subscribe to events and display the event message with each
notification, using a callback method
' specified using lambda expression.

Imports OpcLabs.EasyOpc.AlarmsAndEvents

Namespace DocExamples.AlarmsAndEvents._EasyAEClient

            client.UnsubscribeAllEvents()

            Console.WriteLine("Waiting for 2 seconds...")
            Threading.Thread.Sleep(2 * 1000)
        End Sub
    End Class
End Namespace
```

5.1.3.5 Setting Parameters (OPC A&E)

While the most information needed to perform OPC tasks is contained in arguments to method calls, there are some component-wide parameters that are not worth repeating in every method call, and also some that have wider effect that influences more than just a single method call. You can obtain and modify these parameters through properties on the EasyAEClient object.

Following are instance properties, i.e. if you have created multiple EasyAEClient object, each will have its own copy of them:

- Mode: Allows you to influence how EasyOPC performs various operations on OPC Alarms and Events servers.
- HoldPeriods: Specifies optimization parameters that reduce the load on the OPC server.

Instance properties can be modified from your code.

In OPC Data Client.NET, if you have placed the EasyAEClient object on the designer surface, the instance properties can also be directly edited in the Properties window in Visual Studio.

In OPC Data Client-COM, your code can set different values to these properties if needed.

Following properties are static, i.e. shared among all instances of EasyAEClient object:

- EngineParameters: Contains global parameters such as frequencies of internal tasks performed by the component.
- MachineParameters: Contains parameters related to operations that target a specific computer but not a specific OPC server, such as browsing for OPC servers using various methods.
- ClientParameters: Contains parameters that influence operations that target a specific OPC server a whole.
- LinkParameters: Contains parameters that influence how EasyOPC works with live OPC event subscriptions.

Static properties can only be modified from your code.

Please use the Reference documentation for details on meaning of various properties and their use.

5.1.4 Imperative Programming Model for OPC UA Alarms & Conditions

This chapter gives you guidance in how to implement the common tasks that are needed when dealing with OPC UA Alarms & Conditions vents server from the client side. You achieve these tasks by calling methods on the EasyUAClient object (the same object as for OPC UA Data Access).

Note: Functionality in this chapter that has to do specifically with Alarms & Conditions is described in Part 9 of the OPC Unified Architecture Specification, however many related and relevant pieces are scattered around other parts of the specification as well.

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

5.1.4.1 Obtaining Information (OPC UA Alarms & Conditions)

For obtaining information related to Alarms & Conditions (such as the state of conditions), OPC UA does not introduce any new mechanism over what we have already described for OPC Data (in OPC UA). Please refer to the “Obtaining Information” under “Imperative Programming Model for OPC Data (Class and UA)” for all necessary information.

Methods (and extension methods) such as EasyUAClient.Read, ReadMultiple, ReadValue, ReadMultipleValues can be used.

5.1.4.2 Modifying Information (OPC UA Alarms & Conditions)

Methods described in this chapter allow your application to modify information in the underlying data source that the OPC server connects to or in the OPC server itself (acknowledging conditions). It is assumed that your application already somehow knows how to identify the data it is interested in. If the location of the data is not known upfront, use methods described Browsing for Information chapter first.

The operations performed by the methods described here are actually implemented inside the OPC server. The OPC specification defines OPC UA methods for that, and as such, you could use e.g. one of the EasyUAClient.CallMethod

overloads in order to achieve the same outcome. You would have to, however, look up and specify the Node ID of the desired method, and properly assemble the array of input arguments (with proper types), and so on. The methods described below make it easier, and do the boring part for you. They are all implemented in a specialized client object for OPC UA Alarms and Conditions (EasyUAAlarmsAndConditionsClient Class), which you can derive from the IEasyUAClient, or instantiate standalone.

The easiest way to access the functionality is usually to call the AsAlarmsAndConditionsClient Method on the IEasyUAClient Interface you already have. See **Specialized Client Objects (Section 6.4)** for more details. For an example of how to do that, see **Examples - OPC UA Alarms&Conditions - Acknowledge an event (Section 13.2.6.1)**.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

5.1.4.2.1 Conditions - Disabling/Enabling, and Applying Comments

In order to change a condition instance to the Disabled state, use the IEasyUAAlarmsAndConditionsClient.Disable method.

In order to change a condition instance to the enabled state, use the IEasyUAAlarmsAndConditionsClient.Enable method.

In order to apply a comment to a specific state of a condition instance, use the IEasyUAAlarmsAndConditionsClient.AddComment method.

5.1.4.2.2 Dialogs - Responding

In order to respond to pass the selected response option and end the dialog, use the IEasyUAAlarmsAndConditionsClient.Respond method.

5.1.4.2.3 Acknowledgeable Conditions - Acknowledging and Confirmation

In order to acknowledge an event notification for a condition instance state (where AckedState is FALSE), use the IEasyUAAlarmsAndConditionsClient.Acknowledge extension method.

```

In order to confirm an event notification for a condition instance state (where ConfirmedState is FALSE), use the IEasyUAAlarmsAndConditionsClient.Confirm method.

5.1.4.2.4 Alarms - Shelving and Unshelving

In order to set the alarm condition to the Unshelved state, use the IEasyUAAlarmsAndConditionsClient.Unshelve extension method.

In order to set the alarm condition to the TimedShelved state, use the IEasyUAAlarmsAndConditionsClient.TimedShelve extension method.

In order to set the alarm condition to the OneShotShelved state, use the IEasyUAAlarmsAndConditionsClient.OneShotShelve method.

5.1.4.3 Browsing for Information (OPC UA Alarms & Conditions)

OPC Data Client contains methods that allow your application to retrieve and enumerate information about OPC UA Alarm & Conditions servers that exist on the network, and data available within these servers. Your code can then make use of the information obtained, e.g. to accommodate to configuration changes dynamically.

The methods we are describing here are for programmatic browsing, with no user interface (or when the user interface is provided by our own code).

5.1.4.3.1 Discovering OPC UA Servers (OPC UA Alarms & Conditions)

Please refer to the “Discovering OPC UA Servers” chapter under “Imperative Programming Model for OPC Data (Class and UA)” for all necessary information. OPC Unified Architecture, as the name suggests, allows to treat multiple functionality areas commonly, and the same OPC Servers that provide Data Access functionality are (or can be) also Alarms & Conditions servers.

5.1.4.3.2 Browsing for OPC UA Event Sources

In order to browse for event sources, you can use the pre-made browse parameters available in

the UABrowseParameters.EventSources static property, and call the IEasyUAClient.Browse Method with them. Alternatively, you can use a dedicated extension method, IEasyUAClient.BrowseEventSources, to perform browsing for event sources easily.

5.1.4.3.3 Browsing for OPC UA Notifiers

In order to browse for notifiers, you can use pre-made browse parameters available in the UABrowseParameters.Notifiers static property, and call the IEasyUAClient.Browse method. Alternatively, you can use a dedicated extension method, IEasyUAClient.BrowseNotifiers, to perform browsing for notifiers easily.

C#

```
// This example shows how to browse objects under the "Objects" node and display
notifiers.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.OperationModel;
```

```
namespace UADocExamples.AlarmsAndConditions
{
    class BrowseNotifiers
    {
        public static void Overload2()
        {
            // Start browsing from the "Objects" node
            try
            {
                BrowseFrom(UAObjectIds.ObjectsFolder);
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message);
            }
        }

        private static void BrowseFrom(UANodeDescriptor nodeDescriptor)
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:62544/Quickstarts/AlarmConditionServer";

            Console.WriteLine();
            Console.WriteLine();
            Console.WriteLine("Parent node: {0}", nodeDescriptor);

            // Instantiate the client object
            var client = new EasyUAClient();

            // Obtain notifiers
            UANodeElementCollection notifierNodeElementCollection =
client.BrowseNotifiers(
                endpointDescriptor, nodeDescriptor);

            // Display notifiers
            if (notifierNodeElementCollection.Count != 0)
            {
                Console.WriteLine();
                Console.WriteLine("Notifiers:");
                foreach (UANodeElement notifierNodeElement in
notifierNodeElementCollection)
                    Console.WriteLine(notifierNodeElement);
            }

            // Obtain objects
            UANodeElementCollection objectNodeElementCollection = client.BrowseObjects(
                endpointDescriptor, nodeDescriptor);

            // Recurse
            foreach (UANodeElement objectNodeElement in objectNodeElementCollection)
                BrowseFrom(objectNodeElement);
        }

        // Example output (truncated):
        //

5.1.4.4 Subscribing to Information (OPC UA Alarms & Conditions)

If your application needs to be informed about events occurring in the process and provided by the OPC UA Alarms & Conditions server, it can subscribe to them, and receive notifications.

OPC Data Client contains methods that allow you to subscribe to OPC events, change the subscription parameters, and unsubscribe.

5.1.4.4.1 Subscribing to OPC UA Events

Generally speaking, you subscribe to OPC UA Events similarly to data changes, but by using monitoring parameters that contain an event filter instead of data change filter. Besides the UAMonitoringParameters.DataChangeFilter property, the UAMonitoringParameters class also has an EventFilter property (of UAEventFilter type). The developer can specify either a data change filter, or an event filter, with monitoring parameters.

In This Topic

As the UAMonitoringParameters are part of the information that gets passed (directly or indirectly) to any EasyUAClient.SubscribeMonitoredItem or SubscribeMultipleMonitoredItems call, the introduction of the EventFilter property and the EventNotification event (both described above) are, in fact, the only core features that already in itself allow the Alarms & Conditions support to work. Many other features simply provide better developer experience above this.

A single event

Instead of putting together the monitoring parameters with an event filter, you can subscribe to events a bit easier using the IEasyUAClient.SubscribeEvent extension method, with several overloads. Similarly to the IEasyUAClient.SubscribeDataChange extension method (for data changes), the SubscribeEvent method provides a simplified way to subscribe to events.

C#

```
// This example shows how to subscribe to event notifications and display each incoming event.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.AlarmsAndConditions
{
    partial class SubscribeEvent
    {
        public static void Overload1()
        {
            // Define which server we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:62544/Quickstarts/AlarmConditionServer";

            // Instantiate the client object and hook events
            var client = new EasyUAClient();
            client.EventNotification += client_EventNotification;

            Console.WriteLine("Subscribing...");
            client.SubscribeEvent(endpointDescriptor, UAObjectIds.Server, 1000);

            Console.WriteLine("Processing event notifications for 30 seconds...");
            System.Threading.Thread.Sleep(30 * 1000);

            Console.WriteLine("Unsubscribing...");
            client.UnsubscribeAllMonitoredItems();

            Console.WriteLine("Waiting for 5 seconds...");
            System.Threading.Thread.Sleep(5 * 1000);
        }

        static void client_EventNotification(object sender, EasyUAEventNotificationEventArgs
e)
        {
            // Display the event
            Console.WriteLine(e);
```

```
        }

Multiple events

Multiple events are more efficiently subscribed using the SubscribeMultipleMonitoredItems method:

C#

```
// This example shows how to subscribe to multiple events.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.AlarmsAndConditions;
using OpcLabs.EasyOpc.UA.Filtering;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.AlarmsAndConditions
{
    class SubscribeMultipleMonitoredItems
    {
        public static void Events()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:62544/Quickstarts/AlarmConditionServer";

            // Instantiate the client object and hook events
            var client = new EasyUAClient();
            client.EventNotification += client_EventNotification;

            Console.WriteLine("Subscribing...");
            client.SubscribeMultipleMonitoredItems(new[]
                {
                    new EasyUAMonitoredItemArguments("firstState",
                            endpointDescriptor,
                        UAObjectIds.Server,
                        new UAMonitoringParameters(1000, new UAEventFilterBuilder(

5.1.4.4.2 Specifying Event Filters (OPC UA Alarms & Conditions)

The UAEventFilter object (used for specifying the event filters) is probably the most complicated part of the OPC UA Alarms & Condition features. It has two main parts: Select clauses (contained in the SelectClauses property, of UAAttributeFieldCollection type), and a Where clause (contained in the WhereClause property, of UAContentFilterElement type). The Select clauses contain a collection of the attribute fields to return with each event in a notification. The Where clause contains the criteria limiting the notifications.

In order to make the creation of some event filters appear shorter in the code, a UAEventFilterBuilder class is provided. Instances of this builder can be implicitly converted to the event filter itself (hence you can create just the UAEventFilterBuilder objects, and use them at all places where the UAEventFilter object is expected). The builder contains a Where clause, and is a collection of Select clauses. You can therefore use the C# collection initializer to specify the Select clauses.

In COM (tools like VB6, Delphi etc.), creation of OPC UA Event Filters requires longer code. For related information, see http://kb.opclabs.com/Creating_an_OPC_UA_event_filter_in_COM .

5.1.4.4.2.1 The Select clauses

Each Select clause of the event filter is a UAAttributeField object, which contains an Operand property. You can optionally set its the State property to an object of your choice, and the same object will then be made available to you in the event notification containing the operand. An Operand is of the UASimpleAttributeOperand type,

and specifies primarily a TypeId node in the server, and a QualifiedNames collection (of UAQualifiedNameCollection type), which is a so-called simple relative path (inside that type) that leads to the required node. A simple relative path can only contain forward, "any hierarchical" references.

Conversion methods, and conversion operators exist between the UAQualifiedNameCollection (for simple relative paths) and UABrowsePathElementCollection (for general relative paths). Conversion from UAQualifiedNameCollection to UABrowsePathElementCollection is always possible and has an implicit conversion operator, conversion from UABrowsePathElementCollection to UAQualifiedNameCollection is only possible for simple relative path, and has an explicit conversion operator instead.

In order to make the specification of the most commonly used Select clauses easier, it is possible to use pre-defined clauses provided in the static UABaseEventObject.Operands class (for example, UABaseEventObject. Operands.Message). The UABaseEventObject.AllFields property can be used to obtain Select clauses for all fields of the UA base event type at once.

C#

5.1.4.4.2.2 The Where clause

The Where clause of the event filter is represented using the UAContentFilterElement object. This objects contains the filter operand to be evaluated (the FilterOperator property, which is a UAFilterOperator enumeration), and the operands used by the selected operator (the FilterOperands property, which is a UAFilterOperandCollection). The UAFilterOperator enumeration contains all operators supported by OPC UA (Equals, IsNull, GreaterThan, LessThan, GreaterThanOrEqual, LessThanOrEqual, Like, Not, Between, InList, And, Or, Cast, InView, OfType, RelatedTo, BitwiseAnd, BitwiseOr). The UAFilterOperandCollection is a collection of content filter operands (UAFilterOperand).

The UAFilterOperand is a base class for four different types of filter operands: UAAttributeOperand (an operand consisting of an attribute of a node in a type, with optional relative path and alias), UAContentFilterElement (essentially, an operator with operands), UALiteralOperand (an operand consisting of a literal value), or UASimpleAttributeOperand (an operand consisting of an attribute of a node in a type, with optional simple relative path, and no alias).

In order to make the creation of Where clauses appear shorter in the code, a UAContentFilterElementBuilder class is provided. Instances of this builder can be implicitly converted to the content filter element itself (hence you can create just the UAContentFilterElementBuilder objects, and use them at all places where the UAContentFilterElement object is expected). The builder contains an operator and is a collection of operands; you can use the C# collection initializer to specify the operands.

For further simplification of the coding, the UAFilterElements static class provides an easy way to construct basic filter elements (literal, attribute, or a simple attribute), and elements with various operators. Using the UAFilterElements class is for most cases the recommended way to create the Where clause of the event filter. For example, UAFilterElements.GreaterThanOrEqual creates a Where clause with the '>=' operator. There are methods for each of the OPC UA operators, with various overloads. The UAFilterElements.Attribute, UAFilterElements.Literal and UAFilterElements.SimpleAttribute methods can be used to create other types of filter elements. Moreover, useful overloads exist that assure that you can actually use .NET objects directly as values of operands, and they will be interpreted as literal elements. With use of all these code simplifying features, you can write, for example, the following Where clause:

```
UAFilterElements.GreaterThanOrEqual(UABaseEventObject.Operands.Severity, 500).
```

C#

```
// This example shows how to specify criteria for event notifications.

5.1.4.4.3 Changing Existing Subscription (OPC UA Alarms & Conditions)

It is not necessary to unsubscribe and then subscribe again if you want to change parameters of existing subscription, such as its sampling interval, or the event filter. Instead, change the parameters by calling the ChangeMonitoredItemSubscription method, passing it the subscription handle, and the new parameters.

For changing parameters of multiple subscriptions in an efficient manner, call the ChangeMultipleMonitoredItemSubscriptions method.

5.1.4.4.4 Unsubscribing from OPC UA Events

If you no longer want to receive event notifications, you need to unsubscribe from them. To unsubscribe from a single monitored item, call the UnsubscribeMonitoredItem method, passing it the (event) subscription handle. To unsubscribe from events in an efficient manner, call the UnsubscribeMultipleMonitoredItems method (instead of calling UnsubscribeMonitoredItem in a loop), passing it an array of (event) subscription handles.

You can unsubscribe from all monitored items you have previously subscribed to (on the same instance of EasyUAClient object) by calling the UnsubscribeAllMonitoredItems method.

5.1.4.4.5 Refreshing Condition States (OPC UA Alarms & Conditions)

The UAMonitoredItemArguments class contains a Boolean AutoConditionRefresh property. When set (this is the default), a UA ConditionRefresh will be automatically performed when needed to keep the condition information up-to-date.

The component handles special events reserved for condition refresh automatically, and translates them to event notifications with a special form of event arguments. Event notifications (EasyUAEventNotificationArgs) that related to condition refresh have their Refresh property set to 'true'. In addition, a start of condition refresh is indicated by a

notification with event arguments that have their RefreshInitiated property set to 'true'. Correspondingly, an end of condition refresh is indicated by a notification with event arguments that have their RefreshComplete property set to 'true'.

5.1.4.4.6 OPC UA A&C Notification Event

When an OPC UA Alarms & Conditions server generates an event, the EasyUAClient object generates an EventNotification event. For subscription mechanism to be useful, you should hook one or more event handlers to this event. This event is raised for every event generated by a subscribed OPC monitored item.

To be more precise, the EventNotification event is actually generated in other cases, too - if there is any significant occurrence related to the event subscription. This can be for three reasons:

1. You receive the EventNotification when a successful connection (or re-connection) is made. In this case, the Exception and EventData properties of the event arguments are null references.
2. You receive the EventNotification when there is a problem with the event subscription, and it is disconnected. In this case, the Exception property contains information about the error. The EventData property is a null reference.
3. You receive one additional EventNotification when the component is about to send you notifications for condition refresh, and one additional EventNotification after the component has sent you all notifications for the condition refresh. In these cases, the RefreshInitiated or RefreshComplete property of the event arguments is set to 'true', and the Exception and EventData properties contain null references.

The notification for the EventNotification event contains an EasyUAEventNotificationEventArgs argument. You will find all kind of relevant data in this object. Some properties in this object contain valid information under all circumstances - e.g. Arguments (including Arguments.State). Other properties, such as EventData, contain null references when there is no associated information for them. When the EventData property is not a null reference, it contains a UAEventData object describing the detail of the actual OPC event received from the OPC UA Alarms & Conditions server.

Before further processing, your code should always inspect the value of Exception property of the event arguments. If this property is not a null reference, there has been an error related to the event subscription, the Exception property contains information about the problem, and the EventData property does not contain a valid object.

If the Exception property is a null reference, the notification may be informing you about the fact that a condition refresh is being initiated or is complete (in this case, the RefreshInitiated or RefreshComplete property is 'true'), or that an event subscription has been successfully connected or re-connected (in this case, the EventData property is a null reference). If none of the previous applies, the EventData property contains a valid UAEventData object with details about the actual OPC event generated by the OPC server.

Pseudo-code for the full EventNotification event handler may look similar to this:

> **if** notificationEventArgs.Exception is not null **then**
>
> *An error occurred and the subscription is disconnected, handle it (or ignore)*
>
> **else if** notificationEventArgs.RefreshInitiated **then**
>
> *A "refresh" has been initiated; handle it*
>
> **else if** notificationEventArgs.RefreshComplete **then**
>
> *A "refresh" is complete; handle it*
>
> **else if** notificationEventArgs.EventData is null **then**
>
> *Subscription has been successfully connected or re-connected, handle it (or ignore)*
>
> **else**
>
> *Handle the OPC event, details are in notificationEventArgs.EventData. You may use notificationEventArgs.Refresh flag for distinguishing refreshes from original notifications.*

The EventNotification event handler is called on a thread determined by the EasyUAClient component. For details, please refer to "Multithreading and Synchronization" chapter under "Advanced Topics".

The arguments of each event notification (EasyUAEventNotificationEventArgs) have an EventData property (of type UAEventData, described further below), which contains details about the OPC UA event. In addition, common information such as the copy of the input arguments to the subscription, i.e. identification of the endpoint and node (monitored item) which has generated the event, is included. The Exception property (and several related properties) indicates success (when it is a null reference), or a failure (in which case it contains an exception object describing the error).

The UAEventData object contains details about an OPC UA event, i.e. the information that the OPC UA server sends with the event notification. Primarily, it has a FieldResults property, which is a dictionary containing results for each of the fields in the select clauses of the event filter. Each field results is a ValueResult object, i.e. it can either contain the actual value, or an error indication.

```

In order to make access to at least some of these results easier (without having to go through indexing an element in the dictionary), the UAEventData object also contains a BaseEvent property (of UABaseEventObject type). The UABaseEventObject class contains properties that directly correspond to information contained in the base event type (from which all UA events are derived), such as SourceName, Time, Message, Severity, etc. In case of an error related to a particular field, the corresponding property will contain its default value (e.g. an empty string for a Message).

            Console.WriteLine("Severity: {0}", baseEventObject.Severity)
        End Sub
    End Class
End Namespace
```

It should be noted that the FieldResults directory always contains results for the fields you have specified in Select clause of the event filter, but it can contain some additional fields as well. This happens when these fields are necessary for internal processing inside the component. Your code should be able to ignore the results that it has not requested.

Note: Some data returned use complex data types defined by OPC UA, which OPC Data Client transforms to its own .NET types. For example, the UATimeZoneData class contains data returned in the UABaseEventObject.LocalTime property (defines the local time that may or may not take daylight saving time into account).

5.1.4.4.7 Using Callback Methods Instead of Event Handler (OPC UA Alarms & Conditions)

The subscription methods also allow you to directly specify the callback method (delegate) to be invoked for each event notification you are subscribing to.

For detailed discussion on this subject, please refer to "Using Callback Methods Instead of Event Handlers" under the "OPC Data Access Tasks" chapter. All information presented there applies to OPC UA Alarms & Conditions as well.

The EasyUAMonitoredItemArguments object has an EventCallback property. This property specifies an optional method to be invoked for each event notification generated by the monitored item.

There is also an IEasyUAClient.SubscribeMonitoredItem extension method overload that accepts an event callback (EasyUAEventNotificationEventHandler).

C#

```
// This example shows how to subscribe to event notifications and display each incoming
event
// using a callback method that is provided as lambda expression.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;

namespace UADocExamples.AlarmsAndConditions
{
    partial class SubscribeEvent
    {
        public static void CallbackLambda()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:62544/Quickstarts/AlarmConditionServer";

            // Instantiate the client object
            var client = new EasyUAClient();

            Console.WriteLine("Subscribing...");
            // The callback is a lambda expression the displays the event
            client.SubscribeEvent(
                endpointDescriptor,
                UAObjectIds.Server,
                1000,
                (sender, eventArgs) => Console.WriteLine(eventArgs));
            // Remark: Production code would check e.Exception before accessing
e.EventData.
```

```
            Console.WriteLine("Processing event notifications for 30 seconds...");
            System.Threading.Thread.Sleep(30 * 1000);

            Console.WriteLine("Unsubscribing...");
            client.UnsubscribeAllMonitoredItems();

            Console.WriteLine("Waiting for 2 seconds...");
            System.Threading.Thread.Sleep(2 * 1000);
        }
    }
}
```

VB.NET

```
' This example shows how to subscribe to event notifications and display each incoming
event
' using a callback method that is provided as lambda expression.

Imports OpcLabs.EasyOpc.UA
Imports OpcLabs.EasyOpc.UA.AddressSpace.Standard

        End Sub
    End Class
End Namespace
```

5.1.4.5 Setting Parameters (OPC UA Alarms & Conditions)

As the Alarms & Conditions support for OPC UA uses the same EasyUAClient object, the same properties and objects are used for setting the parameters as for OPC Data. Please refer to the "Setting Parameters" chapter under "Imperative Programming Model for OPC Data (Class and UA)" for all necessary information.

5.1.5 Imperative Programming Model for OPC UA PubSub

This chapter gives guidance in implementing common tasks when dealing with data made available over OPC UA PubSub. You achieve these tasks mainly by calling methods on the EasyUASubscriber object. Depending on what you need, see:

Subscribing to Information (OPC UA PubSub) (Section 5.1.5.1)

- **Subscribing to Information (OPC UA PubSub) (Section 5.1.5.1)**
- **Accessing OPC UA PubSub Configuration Model (Section 5.1.5.2)**
- **OPC UA Publish-Subscribe Client (Section 6.4.3)**

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

OPC UA PubSub is a large specification, and not all its parts are commonly used and have the same significance. OPC Data Client implements the parts that are relevant for its purpose. Some parts OPC UA PubSub functionality is not available in OPC Data Client. The parts that are not (yet) available include:

- Publisher and server functionality.
- JSON message mapping.
- AMQP transport protocol mapping.
- MQTT transport protocol mapping.
- Support for message signing and encryption.
- Custom data types.
- PubSub discovery.
- PubSub security key service model.
- Write access to PubSub configuration.
- Parts of PubSub configuration that relate to subscriber configuration.

> 💡 Most of the OPC UA PubSub examples work with the **OPC UA Demo Publisher (Section 11.5.5)** that is installed with the product, or can be downloaded separately. It supports both Windows and Linux.

5.1.5.1 Subscribing to Information (OPC UA PubSub)

Subscribing to dataset messages

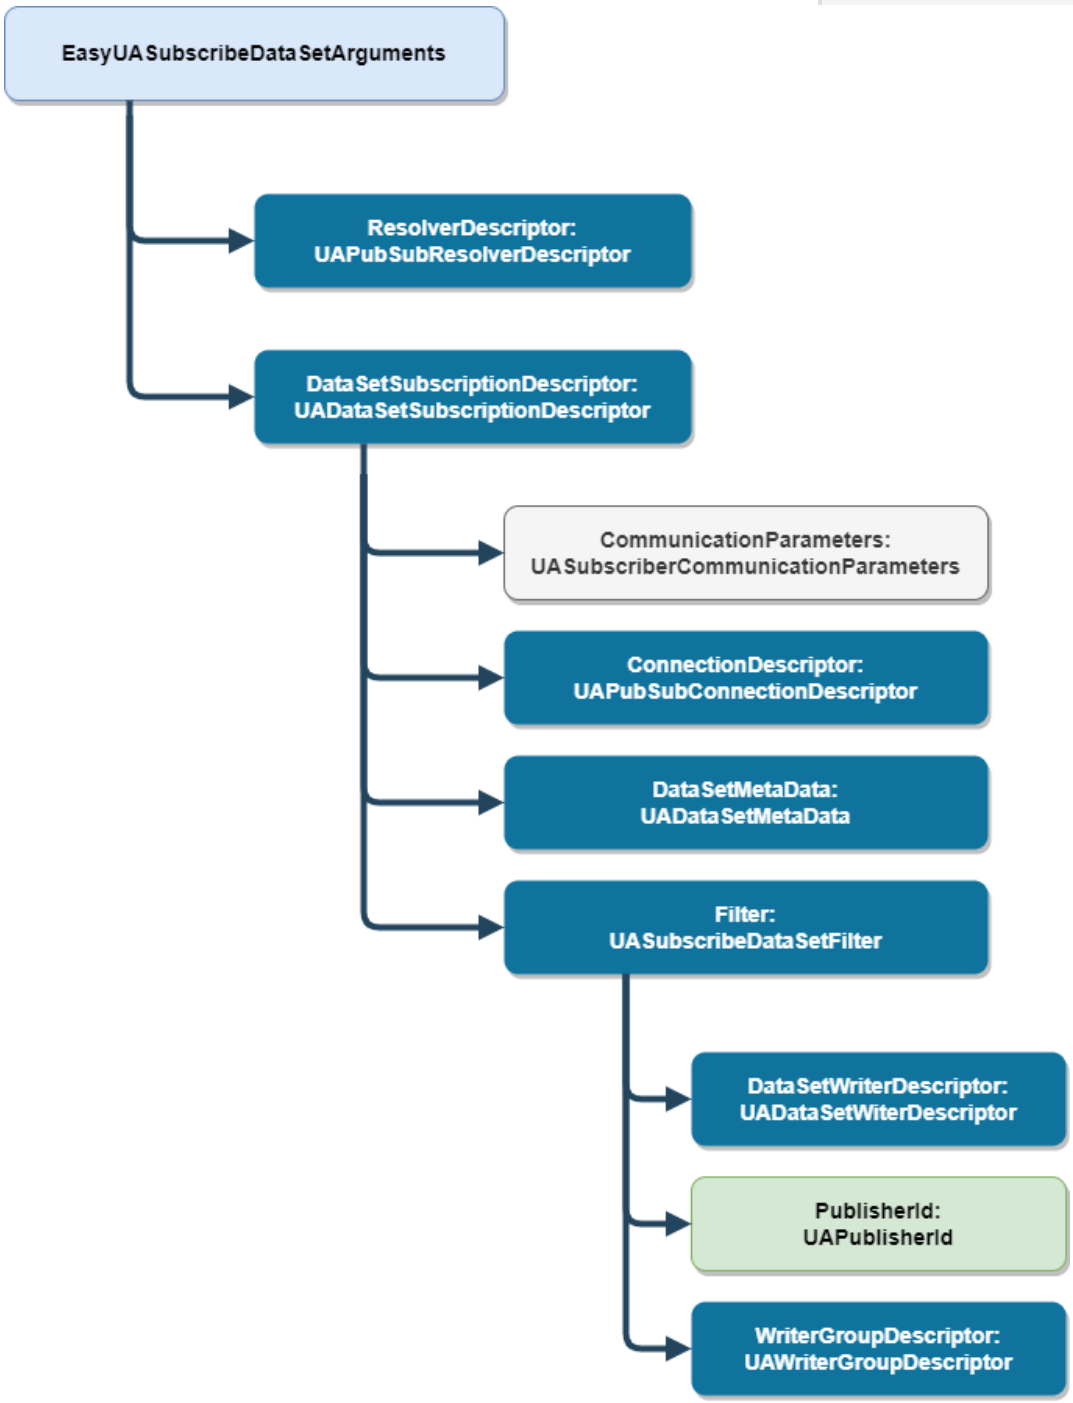
> 💡 For quick tests and experiments with OPC UA PubSub, and especially if you do not want to lose time coding when you need to figure out the proper settings, you can use the **OpcCmd Utility (Section 11.4)** - see Using OpcCmd Utility as OPC UA PubSub Subscriber. The utility allows to specify all parameters of the dataset subscriptions that are accessible from code, but simply by entering them on the command line. It also has a built-in support for displaying the incoming datasets and their fields.

A subscription is initiated by calling the SubscribeDataSet Method on the EasyUASubscriber Class. In its

In This Topic

basic form, the method takes a single argument which is an instance of the EasyUASubscribeDataSetArguments Class, and this argument contains all the information necessary to perform the subscription. The object and all the sub-objects it contains are rather complex.

The picture below is meant to give you at least a general overview about what this object contains. There are more "smaller" properties to the individual objects on the picture, but we do not care about them for now.



You can see that the two main parts of the EasyUASubscribeDataSetArguments are:

- the ResolverDescriptor: Is used for **OPC UA PubSub logical resolution (Section 5.1.5.1.4)** only, and
- the DataSetSubscriptionDescriptor: describes the dataset(s) you want to subscribe to.

Inside the dataset subscription descriptor, you always need to specify the PubSub connection, using the ConnectionDescriptor Property. You will typically also need to fill in data in the Filter Property (see **Message Filtering (OPC UA PubSub) (Section 5.1.5.1.2)**), and sometimes provide the DataSetMetaData Property (see **Dataset Metadata (OPC UA PubSub) (Section 5.1.5.1.3)**). The CommunicationParameters Property is used to specify details about the communication, message receive timeout, and parameters specific to message or transport protocol mapping.

> ⚠ When broker transport protocol is in use (such as MQTT or AMQP), you will typically need to specify the broker queue name inside the CommunicationParameters Property.

There are many (extension method) overloads of the SubscribeDataSet Method, with various combinations of arguments. These overloads allow you to bypass the construction of the whole EasyUASubscribeDataSetArguments hierarchy, and pass in simply the parts you need.

The example below subscribes to all dataset messages on an OPC-UA PubSub connection with UDP UADP mapping. The connection is specified by its physical parameters, using the scheme name "opc.udp" and the IP address of the multicast group to listen on.

C#

```
// This example shows how to subscribe to all dataset messages on an OPC-UA PubSub connection with UDP UADP
mapping.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface name to be
used.

using System;
using System.Collections.Generic;
using System.Threading;

```

The example specifies just the PubSub connection, and receives all PubSub messages it encounters. In .NET, it illustrates the use of a SubscribeDataSet Method overload that takes just the PubSub connection descriptor as an input.

Resolved or not?

The information you pass in to the SubscribeDataSet Method may either be used "as is", or it may be subject to **OPC UA PubSub logical resolution (Section 5.1.5.1.4)** first. As explained in **OPC UA PubSub Descriptors (Section 4.12.3)**, you can pass in the physical identifiers, the logical identifiers, or both. The **OPC UA PubSub logical resolution (Section 5.1.5.1.4)** mechanism will be invoked if the dataset subscription descriptor requires resolution (this term is explained in **OPC UA PubSub Descriptors (Section 4.12.3)**).

We can reformulate it so: If you have specified physical identifiers everywhere, they will be directly used, and no logical resolution will take place - even if there are logical identifies filled in as well. If, however, you have a PubSub object somewhere in the descriptors that is only specified by its logical identifier but no physical identifier, the logical resolution mechanism will be used.

Event handlers vs. callback methods

There are two ways your program can be informed about dataset messages that you have subscribed to:

- The EasyUASubscriber invokes event handlers for the DataSetMessage Event. You can hook one or more event handlers to this event.
- You can specify a callback method in the parameters passed to the SubscribeDataSet Method. The callback method is given either by the Callback Property in the EasyUASubscribeDataSetArguments you pass in, or there are extension method overloads to the SubscribeDataSet Method that take a callback parameter directly. The callback method has the same signature as the event handler for the DataSetMessage Event.

It is also possible to specify a non-null callback parameter, and hook an event handler as well. In this case, the callback method will be invoked in addition to the event handlers.

The DataSetMessage event or callback

The event arguments of the DataSetMessage Event are of type EasyUADataSetMessageEventArgs. Because it is indirectly derived from the OperationEventArgs, it contains the Exception Property which is null for success notifications, and non-null in case of failure. You can use the Succeeded Property to make the corresponding test. The actual data of the dataset, if available, is in the DataSetData Property.

The EasyUADataSetMessageEventArgs also contain, in their Arguments Property, a copy of the arguments (EasyUASubscribeDataSetArguments Class) you have used when making the dataset subscription that caused this event or callback. You can use this property to identify the dataset subscription, in case you are using event handlers and have made more subscriptions on the same object, or if you have used the same callback methods with multiple subscriptions. Specifically, the State Property in the EasyUASubscribeDataSetArguments can be used for any information you need to pass from the code that makes the subscription to the code that handles the dataset messages.

The EasyUASubscriber invokes the DataSetMessage event or callback when a new dataset message (you have subscribed to) arrives, but also in some other cases. Below is a list of possible property value combinations and their meaning.

- The Exception Property is null, and the DataSetData Property is also null: Indicates that the PubSub connection (to the message-oriented middleware, depending on the transport protocol) has been successfully established or re-established.
- The Exception Property is null, and the DataSetData Property is not null. A successfully received dataset.
- The Exception Property is not null: Indicates a failure. In this case, the DataSetData Property is always null.

The main causes for failures are

- problems establishing, maintaining or re-establishing the PubSub connection,
- message receive timeouts, and
- inability to decode the message (e.g. due to missing metadata with UADP and RawData encoding).

If the **OPC UA PubSub logical resolution (Section 5.1.5.1.4)** took place, the ResolvedDataSetSubscriptionDescriptor Property is filled in with a dataset subscription descriptor that is derived from the one you have specified when calling the SubscribeDataSet Method, but with the logical identifiers resolved to physical ones.

A typical task when processing the dataset message is to extract one or more fields from the dataset and process them further. The field is identified by its name (or an index in its string form, such "#0", if field names are not available) in the FieldDataDictionary. The example below shows how it can be done.

C#

```
// This example shows how to subscribe to dataset messages and extract data of a specific field.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface name to be
used.

Key Frames and Delta Frames

Depending how OPC UA PubSub is configured, the publisher might be always sending all fields of the dataset with every dataset message, or it may use a combination of *key frames* and *delta frames*. While the key frame dataset message includes values for all fields of the dataset, the delta frame only contains values of the fields that have changed since the previous dataset message.

Key frames and delta frames are a concept that exists purely to spare the network bandwidth. When you subscribe with OPC Data Client, the delta frames are interpreted internally, and a full dataset is always shipped to you in the dataset message event or callback. This way, you do not have to put in any additional code to handle the distinction between key frames and delta frames.

> ⚠ When the publisher uses delta frames, there may be a delay before you start receiving the messages (after the connection is established). This is because OPC Data Client needs to wait for the first key frame until it can start delivering the dataset data to you.

Changing existing subscription

It is not necessary to unsubscribe and subscribe again, if you want to change some parameters of existing subscription, such as its filter (**Message Filtering (OPC UA PubSub) (Section 5.1.5.1.2)**) or the associated metadata (**Dataset Metadata (OPC UA PubSub) (Section 5.1.5.1.3)**). You change the parameters by calling the ChangeDataSetSubscription Method, passing it the dataset subscription handle, and the new parameters in form of an instance of the EasyUADataSetSubscriptionChangeArguments Class.

There is also an extension method (an overload - with the same name) that allows you to easily pass in just the dataset subscription handle, and a new filter.

Unsubscribing

If you no longer want to receive dataset messages, you need to unsubscribe. This is achieved by calling the UnsubscribeDataSet Method, passing it the dataset subscription handle obtained when calling the SubscribeDataSet Method.

Example:

C#

```
// This example shows how to subscribe to dataset messages on an OPC-UA PubSub connection, and then unsubscribe
from that
// dataset.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface name to be
used.

```

You can also unsubscribe from all dataset messages you have previously subscribed to (on the same instance of the EasyUASubscriber Class) by calling the UnsubscribeAllDataSets Method.

Subscriptions are optimized

OPC Data Client merges together requests to the same PubSub objects. If, for example, you make multiple dataset subscriptions and they all use the same PubSub connection, OPC Data Client will only make the connection once.

This merging is performed among all subscriptions on all EasyUASubscriber objects that have their Isolated Property set to 'false' (the default). If you set the Isolated Property on some EasyUASubscriber object to 'true', the merging is then performed on the subscriptions made on that object only.

5.1.5.1.1 Subscriber Communication Parameters (OPC UA PubSub)

The subscriber communication parameters specify details of how the OPC UA PubSub communication is performed. As opposed to the PubSub connection descriptor, which contains parameters needed to establish and maintain the connection to the message-oriented middleware, the subscriber communication parameters are more concerned with the actual communication that takes place after the PubSub connection is established.

The subscriber communication parameters are represented by the UASubscriberCommunicationParameters Class.

There are various communication parameters that can be set, and whether dome of them are used also depends on whether broker-based middleware, or broker-less model is in use.

With broker-based middleware, you will typically need to set the broker queue name in the subscriber communication parameters (unless the logical resolution process provides this information for you). This is done inside the BrokerDataSetReaderTransportParameters Property, which contains sub-parameters used with broker-based middleware. The QueueName Property could be the name of a queue or topic defined in the broker (depending on the terminology used by the protocol in use).

The setting of the broker queue name is illustrated in the example below.

C#

```
// This example shows how to subscribe to all dataset messages on an OPC-UA PubSub connection with
MQTT UADP mapping using
// TCP.
//
// The OpcLabs.MqttNet assembly needs to be referenced in your project (or otherwise made available,
together with its
// dependencies) for the MQTT transport to work. Refer to the documentation for more information.

    }
}
```

In some situations, more communication parameters need to be set - for example, when JSON message mapping is used, and the automatic format recognition provided by OPC Data Client is turned off, such as in the example below.

C#

```
// This example shows how to set parameters specific to JSON message mapping.
//
// The following assemblies need to be referenced in your project (or otherwise made available,
together with their
// dependencies) for the MQTT transport and JSON message mapping to work.
// - OpcLabs.MqttNet
// - OpcLabs.UAPubSubJson
// - Newtonsoft.Json
// Refer to the documentation for more information.

    }
}
```

5.1.5.1.2 Message Filtering (OPC UA PubSub)

By message filtering in OPC UA PubSub, you specify which dataset message should be delivered to your application's code. Parameters that influence the message filtering are part of the dataset subscription descriptor (see **Subscribing to Information (OPC UA PubSub) (Section 5.1.5.1)**).

The various filtering parameters always have a default value that means "no filtering" (on the corresponding piece of message of data). By leaving them all at their defaults, you effectively specify "no filtering whatsoever". You can also set just some of these parameters to the values you are interested in, or you can set all of them.

You need to make a conscious choice about how broad or narrow your filtering will be. In most cases, it is best to define the filter as narrow as possible: Specify the precise publisher, writer group and/or dataset writer etc. that provides the dataset your are interested in. You can then write code (event or callback handlers) that already knows precisely which dataset is coming in, and interpret its contents reliably and easily. Sometimes, however, it makes sense to use a broader filter, and write an event or callback handler that deals with multiple incoming datasets in a generic way. The proper choice of the filter depends on the nature of your project.

In This Topic

> For quick tests and experiments with OPC UA PubSub, and especially if you do not want to lose time coding when you need to figure out the proper settings, you can use the **OpcCmd Utility (Section 11.4)** - see Using OpcCmd Utility as OPC UA PubSub Subscriber. The utility allows to specify all parameters of the dataset subscriptions that are accessible from code, but simply by entering them on the command line. It also has a built-in support for displaying the incoming datasets and their fields.

Subscribe Dataset Filter

In its basic form, the subscribe dataset filter resides in the Filter Property of the UADataSetSubscriptionDescriptor Class, and the dataset subscription descriptor is part of the EasyUASubscribeDataSetArguments that are passed to the SubscribeDataSet Method. There are, however, several extension methods that allow you to make dataset subscription and specify the subscribe dataset filter in a different, easier way, depending on which parts you want to pass in.

Leaving any of the properties of the subscribe dataset filter at its default (initial) value means that no filtering is performed on that piece of information.

The most important parts of the subscribe dataset filter are below.

- PublisherId Property. Specifies the (optional) publisher Id filtering.
- WriterGroupDescriptor Property. Specifies the (optional) writer group filtering.
- DataSetWriterDescriptor Property. Specifies the (optional) dataset writer filtering.

You can also select whether you are interested in data, events, or both (the default), with the properties below.

- AllowDataMessages Property. Determines whether the filter allows (variable) data messages through.
- AllowEventMessages Property. Determines whether the filter allows event messages through.

It is also possibly to specify that you only want to receive dataset messages in which selected fields have certain value. To do, you set the required value under the key (that is a filed name or string form of a filed index) into the dictionary contained in the RequiredFieldValueDictionary Property. The component may, under some circumstances, you the mechanism of so-called promoted fields to achieve the filtering soon in the processing pipeline. This is, however, an implementation detail, and when specifying required field values, you do not have to be concerned about whether the field is promoted or not.

Other Filters

Depending on the message and transport protocol mapping, there may be additional filtering applied to incoming PubSub messages.

For UADP message mapping, several parameters in UAUadpDataSetReaderMessageParameters Class (UadpDataSetReaderMessageParameters in CommunicationParameters Property of the dataset subscription descriptor) acts as filters as well. They are:

- DataSetClassId Property. Defines a dataset class related filter.
- GroupVersion Property. Defines the expected value in the group version field in the header of the network message.
- NetworkMessageNumber Property. The number of the network message inside a publishing interval in which the dataset message is published.

As with the properties on the subscribe dataset filter, leaving these properties at their default (initial) value denotes "no filtering" on that particular piece of information.

There is also, implicitly, a filtering mechanism based on security level of the PubSub message. The SecurityMode Property in the CommunicationParameters of the dataset subscription descriptor describes the minimum security mode of messages that you want to subscribe to. The default settings allows messages with any security mode through.

Data not in the message

You should not specify filtering on data that is not actually transferred in the PubSub messages. If you do, such messages will be filtered out, and you will not receive any useful data.

What does it actually mean? The OPC UA PubSub specification is very flexible, and it allows various pieces of information associated with the message be included or excluded. This may be because such piece of information is not relevant for the task at hand, and/or because (especially in UADP message mapping which is meant to be very terse) for efficiency reasons, the designer of the systems want to eliminate every unnecessary byte to be transferred.

Which information pieces are included or excluded is usually controlled by various flags in the publisher configuration. Some of them (such as optional timestamps) do not relate to filtering. But for those that appear in the filter, you must follow the rules below:

- If publisher Id is not included in the message, the PublisherId Property of the subscribe dataset filter must be kept at UAPublisherId.Null.
- If writer group Id is not included in the message, the WriterGroupDescriptor Property of the subscribe dataset filter must be UAWriterGroupDescriptor.Null.
- If dataset writer Id is not included in the message, the DataSetWriterDescriptor Property of the subscribe dataset filter must be UAWriterGroupDescriptor.Null.
- If dataset class Id is not included in the message, and UADP message mapping is used, the DataSetClassId Property in the UadpDataSetReaderMessageParameters Property must be kept at Guid.Empty.
- If group version is not included in the message, and UADP message mapping is used, the GroupVersion Property in the UadpDataSetReaderMessageParameters Property must be 0.
- If network message number is not included in the message, and UADP message mapping is used, the NetworkMessageNumber Property in the UadpDataSetReaderMessageParameters Property must be 0.
- If a specific field is not included in the message, it should not appear in the RequiredFieldValueDictionary Property of the subscribe dataset filter (although this is not strictly required).

A typical example: You may have access to the publisher configuration, and you will see the concrete, non-zero dataset writer Id of the dataset you are interested in. If the publisher uses the UADP fixed layout (a commonly used profile), the dataset writer id, even though it appears in the publisher's configuration, is not transmitted in the PubSub messages ("on the wire"). Its purpose is served by knowing a concrete data offset (in the message) where the corresponding data starts. In this case, you should not put the dataset writer Id into the subscribe dataset filter.

If you are using **OPC UA PubSub logical resolution (Section 5.1.5.1.4)**, OPC Data Client obtains the information about information included and excluded from the PubSub configuration (the various flags in the publisher configuration). Based on the publisher's configuration, the logical resolution process automatically leaves out the information not included in the PubSub messages from the filters. You therefore need not to do anything special on your side in this case.

Examples

The example below uses a filter that limits the dataset messages received to messages coming from a specific publisher Id, and for a specific dataset writer Id.

C#

```
// This example shows how to subscribe to dataset messages and specify a filter, on an OPC-UA PubSub connection
with
// UDP UADP mapping.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface name to be
used.

5.1.5.1.3 Dataset Metadata (OPC UA PubSub)

In This Topic

The dataset metadata describes the content and semantics of a dataset in OPC UA PubSub. In OPC Data Client, it is represented by an instance of the UADataSetMetaData Class. When you are subscribing to a dataset, metadata is an optional part of the dataset subscription descriptor (UADataSetSubscriptionDescriptor Class), in its DataSetMetaData Property.

The main part of the dataset metadata are field definitions - a metadata for each of the fields contained in the dataset. This is a collection of UAFieldMetaData Class instances, contained in the collection stored in the Fields Property. Each field metadata contains following data members:

- Name Property. The name of the field.
- Description Property. Description of the field.
- DataSetFieldId Property. The unique ID for the field in the dataset, expressed as a string.
- BuiltInType Property. The built-in data type of the field.
- DataTypeId Property. The node Id of the data type of this field.
- MaximumStringLength Property. Specifies the maximum supported length of a String or ByteString.
- ValueRank Property. Indicates whether the data type is an array and how many dimensions the array has.
- ArrayDimensions Property. Specifies the maximum supported length of each dimension.
- DataSetFieldFlags Property. Flags for the field.

Most of the data members have reasonable defaults, and some are not necessary at all times. The Description Property, the DataSetFieldId Property and the DataSetFieldFlags Property are optional. In the most typical case of scalar fields of built-in types, you can leave the DataTypeId Property, the MaximumStringLength Property and the ValueRank Property at their defaults.

Besides the field metadata, the dataset metadata contains some data members that apply to the dataset as a whole. They are:

- Name Property. Name of the dataset.
- Description Property. Description of the dataset.
- ConfigurationVersion Property. The configuration version for the current configuration of the dataset.
- DataSetClassId Property. Provides the globally unique identifier of the class of dataset if the dataset is based on a dataset class.

Do I need the metadata?

The answer is: It depends. Some message mappings (such as JSON) as largely self-descriptive, meaning that even without the metadata, it is possible to decode the dataset messages and event obtain metadata-like information, such as field names, from the dataset message itself. Other message mappings (such as UADP) are more compact, and not fully (or not at all) self-descriptive. The UADP message mapping does not transfer field names in the messages. Consequently, without metadata, OPC Data Client will deliver to you the datasets with field indexes (such as "#0", "#1", ...) instead of field names - but in general, things will work. If you use the UADP message mapping and the dataset is encoded with the RawData encoding (check with the publisher), you **must** have metadata in order to be able to decode the dataset messages.

Where do I get the metadata from?

There are several (or rather, many) ways of obtaining the metadata, and applying them. Below are some of them.

- With **OPC UA PubSub logical resolution (Section 5.1.5.1.4)**, you let OPC Data Client get the metadata from PubSub configuration residing in a standard OPC UA server, or a PubSub configuration file. No additional coding is needed.
- You may access the PubSub configuration from your code, and then retrieve the published dataset element by calling the FindPublishedDataSetElement Method or the GetPublishedDataSetElement Method, and get the dataset metadata from the DataSetMetaData Property of the UAPublishedDataSetElement Class instance.
- You obtain the metadata information in other form (maybe somebody described it in the document, or you read it in your program from some other file format), and you will write code that constructs the instance of the UADataSetMetaData Class. This is described in more details further below.

Defining metadata in code

In order to define the metadata in your code, create an instance of the UADataSetMetaData Class, and fill in its properties and the Fields collection as necessary. Then, assign this dataset metadata instance to the DataSetMetaData Property of the UADataSetSubscriptionDescriptor Class instance that you will use to make your dataset subscription. There are also some extension method overloads of the SubscribeDataSet Method that take the dataset metadata directly as one of their arguments.

In languages like C# or VB.NET, you can take advantage of the fact that the UADataSetMetaData Class support collection initializer syntax for its field, making the code even shorter. This approach is also shown in the example below.

C#

```
// This example shows how to subscribe to dataset messages with RawData field encoding, specifying the metadata necessary
// for their decoding directly in the code.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface name to be used.

using System;

using OpcLabs.EasyOpc.UA.PubSub;
using OpcLabs.EasyOpc.UA.PubSub.Configuration;
using OpcLabs.EasyOpc.UA.PubSub.OperationModel;

namespace UADocExamples.PubSub._EasyUASubscriber
{
    partial class SubscribeDataSet
    {
        public static void Metadata()
        {
            // Define the PubSub connection we will work with. Uses implicit conversion from a string.
            UAPubSubConnectionDescriptor pubSubConnectionDescriptor = "opc.udp://239.0.0.1";
            // In some cases you may have to set the interface (network adapter) name that needs to be used, similarly to
            // the statement below. Your actual interface name may differ, of course.
            //pubSubConnectionDescriptor.ResourceAddress.InterfaceName = "Ethernet";

            // Define the filter. Publisher Id (unsigned 16-bits) is 30, and the writer group Id is 101.
            // The dataset writer Id (1) must not be specified in the filter, because it does not appear in the message.
            var filter = new UASubscribeDataSetFilter(UAPublisherId.CreateUInt16(30), writerGroupDescriptor: 101);

            // Define the metadata, with the use of collection initializer for its fields.
            var metaData = new UADataSetMetaData
            {
                new UAFieldMetaData("BoolToggle", UABuiltInType.Boolean),
                new UAFieldMetaData("Int32", UABuiltInType.Int32),
                new UAFieldMetaData("Int32Fast", UABuiltInType.Int32),
                new UAFieldMetaData("DateTime", UABuiltInType.DateTime)
            };

            // Define the dataset subscription, with specific communication parameters.
            // The dataset offset is needed with messages that do not contain dataset writer Ids and use RawData field
            // encoding. An exception to this rule is when the dataset is the only or first in the dataset message payload,
            // which is also the case here, but we are specifying the dataset offset anyway, for illustration.
            var dataSetSubscriptionDescriptor = new UADataSetSubscriptionDescriptor(
                pubSubConnectionDescriptor, filter, metaData)
            {
                CommunicationParameters = { UadpDataSetReaderMessageParameters = { DataSetOffset = 15 }}
            };

            // Instantiate the subscriber object and hook events.
            var subscriber = new EasyUASubscriber();

Partial metadata

In some cases, partial metadata is sufficient to achieve the purpose. For example, your intent might be to identify dataset fields by their names, but the communication uses UADP mapping, which does not transfer the field names in the messages, and therefore some metadata is required for that. The full metadata, which includes types information for individual fields, is however only needed if RawData encoding is used. If the encoding is Variant or DataValue, type information is not strictly necessary, because dataset data can be decoded based simply on the contents of the dataset message.

You can simplify your code by only specifying field names in the metadata in such cases. This is illustrated in the example below.

C#

```
// This example shows how to subscribe to dataset messages and specify field names, without having the full metadata.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface name to be used.

5.1.5.1.4 OPC UA PubSub logical resolution

The OPC UA PubSub logical resolution is a mechanism that allows you to write code that specifies the information you work in logical terms (symbolic names of PubSub objects), and not in physical terms (such as the various identifier numbers that appear "on the wire").

The logical resolution is automatically used by OPC Data Client if, in the various descriptors you pass into the UnsubscribeDataSet Method, you use a logical identifier (PubSub object name, usually), and do not specify a physical identifier at the same time.

> For quick tests and experiments with OPC UA PubSub, and especially if you do not want to lose time coding when you need to figure out the proper settings, you can use the **OpcCmd Utility (Section 11.4)** - see Using OpcCmd Utility as OPC UA PubSub Subscriber. The utility allows to specify all parameters of the dataset subscriptions that are accessible from code, but simply by entering them on the command line. It also has a built-in support for displaying the incoming datasets and their fields.

In This Topic

Resolver kinds

There are kinds of resolvers, depending on where the data needed for the logical resolution come from.

When the ResolverKind Property in the UAPubSubResolverDescriptor is set to UAPubSubResolverKind.None, the logical resolution cannot be

performed.

Publisher Endpoint Resolver

This resolver is used when the ResolverKind Property in the UAPubSubResolverDescriptor is set to UAPubSubResolverKind.PublisherEndpoint. The resolver connects to an OPC UA server which has the PubSub configuration model, and contains a configuration of the publisher whose messages you want to subscribe to. Based on the publisher configuration and the parameters and logical identifiers and you have specified, the resolver derives the parameters and physical identifiers needed for making the required subscription to the publisher's data.

The OPC UA server that provides the publisher configuration may be integrated with the publisher in the same hardware or software component, but it can also be separate.

When selecting this resolver kind, you need to specify the URL (and possibly other characteristics) of the OPC UA server with the publisher configuration using the PublisherEndpointDescriptor Property in the UAPubSubResolverDescriptor. Instead of creating the PubSub resolver descriptor yourself by setting its kind and the URL, you can call the static Publisher Method and create it in one step.

Publisher File Resolver

This resolver is used when the ResolverKind Property in the UAPubSubResolverDescriptor is set to UAPubSubResolverKind.PublisherFile. The resolver opens a file with PubSub configuration model that contains configuration of the publisher whose messages you want to subscribe to. Based on the publisher configuration and the parameters logical identifiers and you have specified, the resolver derives the parameters and physical identifiers needed for making the required subscription to the publisher's data.

When selecting this resolver kind, you need to specify the PubSub configuration file path and name using the PublisherFileResourceDescriptor Property in the UAPubSubResolverDescriptor. Instead of creating the PubSub resolver descriptor yourself by setting its kind and file name, you can call the static File Method and create it one step.

The configuration file must be in the UABinary format as described in the OPC UA specification (UABinaryFileDataType in Annex A "Common Types" of Part 14).

The use of the publisher file resolver is illustrated in the example below.

C#

```
// This example shows how to subscribe to dataset messages and specify a filter, resolving logical
parameters to physical
// from an OPC-UA PubSub configuration file in binary format. The metadata obtained through the
resolution is used to decode
// fixed layout messages with RawData field encoding.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For
documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface
name to be used.

Resolution rules

When specifying the identifiers for logical resolution, the conditions below must be fulfilled.

- The PubSub objects that you specify by name must exist in the configuration.
- When you specify logical information (such as writer group name or dataset writer name) in the subscribe dataset filter, the PubSub connection must also be described with its logical name.
- When you specify dataset writer name, you must also specify writer group name.
- If you specify both the published dataset name and the dataset writer, the dataset writer must be configured to publish the same dataset.
- If you specify published dataset name, there must be a dataset writer in the configuration that can be used to provide data for the subscription.

In general, there are two approaches that you can take when using the logical resolution (although you can also combine them, and also use

physical identifiers in some places):

- Specify the names of the PubSub connection, the writer group, and the dataset writer.
- Specify the name of the published dataset.

In the first case, the resolution provider finds the specified objects in the configuration, and uses their parameters to determine the proper subscription settings (such the PubSub connection descriptor, communication parameters, and subscribe dataset filter).

In the second case, the resolution provider finds the published dataset in the structure of the dataset folders in the PubSub configuration. It then attempts to find a dataset writer that is configured with this published dataset. Since the same dataset may be published by multiple dataset writers, the algorithm only considers as eligible the dataset writers that reside on PubSub connections with transport profile URI that the component supports.

The example below shows the approach with specifying published dataset name.

C#

```
// This example shows how to subscribe to dataset messages, specifying just the published dataset name,
and resolving all
// the dataset subscription arguments from an OPC-UA PubSub configuration file.
//
// In order to produce network messages for this example, run the UADemoPublisher tool. For
documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to specify the interface
name to be used.

Message Receive Timeout Computation

When resolving from the publisher configuration, the resolution process is sometimes required to provide information that is somewhat difficult to obtain. The most prominent example of this is the MessageReceiveTimeout Property in the UADataSetSubscriptionDescriptor.CommunicationParameters. If you do not specify a non-zero value yourself, what should the resolution process fill in? The only hint it has from the provider configuration is the KeepAliveTime Property in the writer group (UAWriterGroupElement Class). But the keep alive time cannot directly be used as the message receive timeout: There needs to be some tolerance allowed, for computing and network delays. How big this tolerance should be is a big question, and depends on multiple parameters of your system.

In order to provide working results in most cases, the resolution provider uses a linear function to compute the message receive timeout from the keep alive time. The value of the keep alive time is multiple by *message receive timeout factor* (MessageReceiveTimeoutFactor Property), and then a *message receive timeout increase* (MessageReceiveTimeoutIncrease Property) is added to it.

The default message receive timeout factor is 1.05 (i.e. 5% over the keep alive time), and the default message receive timeout increase is 250 milliseconds. Example: For a keep-alive time of 1000 milliseconds, with the default parameters, the resulting message timeout will be 1300 milliseconds. If the computation described here does not work well for you, you can either set the message receive timeout directly to a value you have determined as proper, or you can modify the computation parameters so that they accommodate the keep alive times better to your system.

Data not in the message

When the resolver constructs the subscribe dataset filter (see **Message Filtering (OPC UA PubSub) (Section 5.1.5.1.2)**), it has knowledge about which pieces of data are included in the PubSub messages, and which are excluded. As explained with the subscribe dataset filter, filtering must not be specified on data pieces that are not included in the PubSub messages. The resolver sets the filter properties in such a way that no filtering is specified for information that is excluded from the PubSub messages, and guarantees that the filter will actually work correctly.

Resiliency

The publisher endpoint resolver and the publisher file resolver are *periodic resolvers*. This means that the resolution with them is not normally a one-time occurrence. This allows for long-running programs to achieve resiliency without further programming needed on your part.

If a periodic resolver encounters a failure obtaining the data it needs to perform the resolution, it will retry after a period given by the FailureRetrialDelay Property (in milliseconds). An inaccessibility of the data does not therefore result in permanent loss of the subscription. Note that, however, if there are no problems accessing the data needed to perform the resolution, the resolution will proceed, and if the data is flawed (e.g. in case of an incorrect configuration of the publisher), it may yield subscription parameters that won't work at all, or won't work properly. This kind of error cannot be easily detected.

If a periodic resolver succeeds in obtaining the data it needs to perform the resolution, it will still retry the resolution - but this time, after a period given by the SuccessRetrialDelay Property (in milliseconds). This behavior allows for improper configurations be fixed "on the fly": If there was a configuration error and the resolution yielded dysfunctional result, and the configuration error was later fixed, eventually, the resolver will pick up the new configuration, and make a new resolution, this time with a result that will be functional.

OPC Data Client does not necessarily create separate resolver objects for each dataset subscription you make. Instead, resolvers that use the same data source (e.g. access the same OPC UA server) are shared. For optimization reasons in this scenario, the delays that control the repeated resolution attempts described above are actually further modified by an additional MaximumWaitDelay Property (in milliseconds) in the parameters. This is kind of maximum allowed age of the resolution result. If a retrial has been scheduled for an earlier time, its resolution result will be used (sparing an unnecessary resolution attempt).

The resolver parameters mentioned above are all part of the PeriodicResolverParameters Class instance, stored in static EasyUASubscriber.AdaptableParameters.ResolverParameters.PeriodicResolverParameters Property (if the Isolated Property is set to 'false', which is the default), or in EasyUASubscriber.InstanceParameters.ResolverParameters.PeriodicResolverParameters Property (if you have set the Isolated Property to 'true').

The ResolverAccess Event

For advanced scenarios, your code is informed about certain aspects of the logical resolution process. This is done using the ResolverAccess Event on the EasyUASubscriber Class. With this event, you will receive event arguments that are an instance of EasyUAResolverAccessEventArgs Class. The event arguments contain the ResolverDescriptor Property which tell you the kind of the resolver involved, and its parameters.

The event is raised every time after the resolver accesses its information source. There are two possible outcomes:

- The access has been successful. That it, the resolver could obtain the data it needs to perform the resolution. In this case, the Exception Property in the event arguments is null. Note that the success in obtaining the data needed for resolution does not yet indicate the success of the resolution itself - there can still be errors then, and they are reported through the normal DataSetMessage Event.
- The access has failed. The resolver could not obtain the data it needs to perform the resolution. In this case, the Exception Property in the event arguments is non-null, and it contains information about the failure.

The SubscriptionResolved Event

When the dataset subscription descriptor is successfully resolved, the component raises the SubscriptionResolved Event. This event contains the automatically resolved dataset subscription descriptor in its EasyUASubscriptionResolvedEventArgs.DataSetSubscriptionDescriptor Property. This allows your code to inspect it.

In addition, the event handlers for the SubscriptionResolved Event are allowed to modify the dataset subscription descriptor, and the modifications will be taken over by the component and use d for the actual subscription. This is useful in cases when the automated resolution is not complete, or fully correct.

For example, the PubSub configuration only contains endpoint URLs of Security Key Services (SKS), but no user authentication data with them. The automated resolution fill is in the URLs in the SecurityKeyServices Property of the UAPubSubCommunicationParameters Class, and you can write code inside the SubscriptionResolved Event handled to provide the use authentication information to authenticate the user to the SKS.

The resolved dataset subscription descriptor

In the DataSetMessage Event, after a successful logical resolution, the event arguments contain the final resolved dataset subscription descriptor in the ResolvedDataSetSubscriptionDescriptor Property. The resolved descriptor is derived from the one you passed to the SubscribeDataSet Method, with all the logical identifiers resolved to physical ones, and possible modifications made in the handlers for the SubscriptionResolved Event.

5.1.5.1.5 External OPC UA PubSub packages

In many cases, all code needed to perform OPC UA PubSub functionality is contained directly in core OPC Data Client assemblies. There are some situations, however, when one or more additional pieces of software ("package") is needed.

For more information about the use of communication packages in general, see http://kb.opclabs.com/Using_communication_packages .

In This Topic

OpcLabs.Pcap communication package

OpcLabs.Pcap is an external assembly/package of OPC Data Client that is only needed for:

- OPC UA PubSub Ethernet transport (the "opc.eth" scheme).
- OPC UA PubSub reading or writing Wireshark capture files.

OPC Data Client switches to the OpcLabs.Pcap communication package whenever it detects that any of the above is required. Although OpcLabs.Pcap use does not require anything different from the coding point of view, it requires special handling in several respects - e.g. with regard to licensing, installation, and configuration.

For more information about OpcLabs.Pcap, see http://kb.opclabs.com/OpcLabs.Pcap_communication_package .

MQTT communication packages

MQTT communication is not built-into core OPC Data Client assemblies, but is rather always provided externally, by means of a package that uses some specific MQTT communication library. OPC Data Client automatically uses a default MQTT communication package unless you make a different choice. In case you are fine with the default MQTT communication package selection, you do not need to do anything special in your code, but you still need to make sure that the package is installed and referenced, and you may also want to configure it in some specific way.

For more information about the packages available, see http://kb.opclabs.com/MQTT_communication_packages .

OpcLabs.UAPubSubJson mapping package

This package provides JSON mapping for OPC UA PubSub. It is needed whenever JSON encoding is used in OPC UA PubSub, that is:

- With transport profiles that use JSON message mapping, such as when MQTT or AMQP is used with JSON.
- With transport profiles that use JSON in the message "envelope", such as MQTT version 5.0 (even when the message itself might not be encoded in JSON).

For more information about UAPubSubJson, see http://kb.opclabs.com/OPC_UA_PubSub_JSON_mapping_package .

5.1.5.1.6 Subscribing to a specific dataset field (OPC UA PubSub)

The "native" granular unit of OPC UA PubSub data delivery is a dataset message. The dataset message can contain values of multiple fields. All these field values belong together - they represent a snapshot of some state of the system at a common time point. Individual fields can then be extracted from the dataset message as needed.

There are, however, situations in which your code is only interested in a specific field (or specific fields) of the dataset. For such cases, OPC Data Client offers you a mechanism that allows you to subscribe to individual dataset fields, and the field extraction will be made for you by the component.

In This Topic

This functionality is not available under (or the text does not apply to) COM development platform.

For quick tests and experiments with OPC UA PubSub, and especially if you do not want to lose time coding when you need to figure out the proper settings, you can use the **OpcCmd Utility (Section 11.4)** - see Using OpcCmd Utility as OPC UA PubSub Subscriber. The utility allows to specify all parameters of the dataset subscriptions that are accessible from code, but simply by entering them on the command line. It also has a built-in support for displaying the incoming datasets and their fields.

How-To

Subscribing to specific dataset fields is very similar to subscribing to the whole datasets. A subscription to a single dataset field is initiated by a call to SubscribeDataSetField Method. This is an extension method, with multiple overloads. The primary form takes an argument that is an instance of EasyUASubscribeDataSetFieldArguments Class. This class is very similar to the EasyUASubscribeDataSetArguments Class, but it has an additional FieldName Property, which specifies the name of the dataset field to be subscribed to.

The are various overloads of the SubscribeDataSetField Method, and also various overloads of the EasyUASubscribeDataSetFieldArguments Constructor that allow you to make your subscription code shorter, depending on which pieces of information needed for the subscription you have at hand.

The SubscribeDataSetField Method(s) return an integer (dataset) field subscription handle. Call the UnsubscribeDataSetField Method, passing it this field subscription handle, in order to unsubscribe from the dataset field.

Note that as usual, both the SubscribeDataSetField Method a UnsubscribeDataSetField Method operate asynchronously. That is, you may start receiving callbacks before the SubscribeDataSetField Method returns, and there may be some final callbacks made even after the UnsubscribeDataSetField Method returns.

The callback that you pass in is of type EasyUADataSetFieldMessageEventHandler Delegate, and carries with it event arguments of type EasyUADataSetFieldMessageEventArgs Class. This class is very similar to the EasyUADataSetMessageEventArgs Class, except that instead of the data for the whole dataset message, it contains only data for the particular dataset field that you have subscribed to, in its FieldData Property. Successful establishment of a PubSub connection is indicated by a callback event arguments in which both the Exception Property and FieldData Property contain a null reference.

Pros and Cons

If you just need a specific dataset field, the code becomes simpler with the use of single-field subscriptions. Also, there is no big performance penalty: Even if you subscribe to multiple dataset fields using this mechanism, internally, OPC Data Client makes just one PubSub connection to the message oriented middleware, and also all the message parsing, filtering and most of the processing is made just once. It is only the final message delivery steps that are split, and different.

The disadvantages related to the use of subscriptions to specific dataset fields are:

- You lose the association between the dataset field changes - it is no longer apparent which field values come from the same dataset message.
- You have to use callbacks (not events).
- Does not work in COM.
- They are slightly less efficient with regard to processing speed and memory consumption.

Examples

C#

```
// This example shows how to subscribe to a single dataset field, resolving logical
parameters to physical from an OPC-UA
// PubSub configuration file in binary format. The metadata obtained through the
resolution is used to decode fixed layout
// messages with RawData field encoding.
//
// In order to produce network messages for this example, run the UADemoPublisher tool.
For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.

using System;
using System.Threading;
using OpcLabs.EasyOpc.UA.PubSub;

5.1.5.2 Accessing OPC UA PubSub Configuration Model

Introduction

In This Topic

PubSub configuration describes the parameters of an OPC UA publisher and/or subscriber. It can be stored in a file, or it can be accessed through an information model in a "normal" OPC UA server.

Note that the use of PubSub configuration model is entirely optional. The model is standardized in OPC UA specifications, and when used, it must be used "as is". But, OPC UA publishers and subscribers may not use the configuration model at all, or they may choose to expose their configuration is some different way.

> If your intent is to use the PubSub configuration to find data that would allow you to set up a PubSub subscription, you can use the built-in **OPC UA PubSub logical resolution (Section 5.1.5.1.4)** mechanism instead. This will save you lots of work.

> Currently, OPC Data Client only provides a read-only view of the PubSub configuration. That is, you cannot use OPC Data Client to change anything in the PubSub configuration.

You can obtain the IUAReadOnlyPubSubConfiguration Interface by calling appropriate methods on the **OPC UA Publish-Subscribe Client (Section 6.4.3)**.

Concepts

Most PubSub objects in the PubSub configuration are identified by their names. The name is usually a string, but some PubSub object are identified by an instance of UAQualifiedName Class.

Depending on the type of PubSub object and the structure of other arguments, sometimes a simple name of the PubSub object is enough to unambiguously locate it in the PubSub configuration. In other cases, the name is not sufficient, and a locator has to be used.

In this context, locator is a structure that consists of two or more names of PubSub objects. The names together unambiguously determine the location of the PubSub object in the PubSub configuration. For example, a dataset writer locator (represented by the UADataSetWriterLocator Class) contains

- a PubSub connection name,
- a writer group name, and
- a dataset writer name.

Published datasets are organized in a tree of dataset folders. Each published dataset has a name that must be unique not only in its dataset folder, but across the whole PubSub configuration. If a location of a published dataset in the PubSub configuration needs to be specified, a dataset folder path is used. The dataset folder path is a sequence of dataset folder names, starting from the root of the dataset folder tree.

Because published dataset names are unambiguous across the whole PubSub configuration, some methods allow you to omit the dataset folder path. In such case, you can pass a null reference in place of the dataset folder path, and the method will work on the whole tree. Note that a null reference in place of a dataset folder path is different from an empty path (a non-null, empty sequence): An empty dataset folder path denotes a "root" folder.

Some more information related to OPC UA PubSub configuration can be found in **OPC UA PubSub logical identifiers (Section 4.12.2)**.

Functionality

The methods available on the PubSub configuration allow you to look up PubSub objects using various criteria, and retrieve their data. They are grouped into several categories.

Looking up and searching for PubSub objects

PubSub objects can be looked up using their names. Methods that allow you to look up certain type of object in the PubSub configuration (sometimes given the location of their logical parent) are consistently called FindXXXX, where XXXX determines the type of PubSub object being looked up.

Attempt to look up an object that does not exist is not considered an error. When any of the FindXXXX does not find the PubSub object being looked up, it does not throw an exception. Instead, it simply returns a null reference. If the method call, however, contains argument that give location where the lookup is to be performed (e.g. the name of the PubSub connection when looking for a writer group), this location must be valid, otherwise an error occurs (UALogicalException Class).

List of the FindXXXX methods is below.

- FindConnectionElement Method
- FindDataSetWriterElement Method
- FindPublishedDataSetElement Method
- FindWriterGroupElement Method

If you need to look for a published dataset (by its name) in a given dataset folder and its subfolders, use the SearchPublishedDataSet Method.

Determining PubSub object presence

In most cases, you can use one of the FindXXXX methods to determine whether a certain PubSub object is present in the PubSub configuration. The PubSub object with the given name is present if the result of the FindXXXX method is not null. Alternatively, you can use one of the ListXXXX methods, and check whether the PubSub object name is among those returned.

You can use the above described approaches, except:

- when you need to determine whether a certain dataset folder exists, there is no FindDataSetFolder method (because there is no additional information for the dataset folder besides its name). In this case, use the HasDataSetFolder Method.
- when you need to determine whether a certain extension field exists in a specified published dataset. In this case, use the HasExtensionField Method.

The methods to determine the PubSub object presence are consistently named HasXXXX, where XXXX determines the type of PubSub object being tested for existence.

Getting PubSub object names and locators

If you do not know the names of certain PubSub objects, you can obtain the names from the PubSub configuration, usually given the location of some kind of logical parent. The methods that return the list of such names (or locators) are consistently called ListXXXX, where XXXX determines the type of PubSub object.

The methods below return names or locators of PubSub objects residing under a given parent.

- ListDataSetFolderNames Method
- ListDataSetWriterLocators Method
- ListDataSetWriterNames Method
- ListExtensionFieldQualifiedNames Method
- ListPublishedDataSetNames Method
- ListPubSubConnectionNames Method
- ListWriterGroupNames Method

There are also utility methods, built on top of others, that provide data about PubSub objects combined from multiple locations. They are briefly described below.

- ListAllConnectionDataSetWriterLocators Method. Gets locators of all dataset writers on a specified PubSub connection.
- ListAllDataSetWriterLocators Method. Gets locators of all dataset writers in the whole PubSub configuration.
- ListAllPublishedDataSetNames Method. Gets names of all published datasets in the PubSub configuration.

Retrieving PubSub objects

Methods that retrieve PubSub objects from the configuration are consistently named using the GetXXXX pattern. In most cases, a PubSub object can be retrieved by looking it up using one of the FindXXXX methods described above. For the remaining information in the PubSub configuration that cannot be accessed in this way, use one of the methods below.

- GetMultipleExtensionFieldValues Method (or, if you need just one extension field, GetExtensionFieldValue Method).
- GetPublishedDataSetSourceElement Method

- GetPubSubConfigurationElement Method

The published dataset can optionally be associated with a published dataset source. The information about the published dataset source can be retrieved using the GetPublishedDataSetSourceElement Method. Because the published dataset source is optional, this method (and the methods that are derived from it - see further) returns null when the published dataset source is not configured - this is a difference from all other GetXXXX methods which never return null. The result of the GetPublishedDataSetSourceElement Method is polymorphic - its type depends on the type of the published dataset source, and it can be an instance of either UAPublishedDataItemsElement Class or UAPublishedEventsElement Class. If you know upfront which type of published dataset source you expect, you can use one of the extension methods, the GetPublishedDataItemsElement Method or GetPublishedEventsElement Method, to directly retrieve the desired type; they give an error if the actual type is not what you have coded for.

The methods below provide basically a functionality of the corresponding FindXXXX methods, with the difference that the PubSub object being looked up must exist; if not, the method gives an error. Consequently, in case of successful completion of any of these methods, the return value is never null.

- GetConnectionElement Method
- GetDataSetWriterElement Method
- GetPublishedDataSetElement Method
- GetWriterGroupElement Method

Sometimes you need to retrieve information for all child objects under certain parent. This is, in fact, a combination of a ListXXXXNames method and one of the GetXXXXElement methods above. For convenience, OPC Data Client provides (extension) methods for this functionality already. The return type is always a keyed collection of elements, where the key is the name. The methods in this group are given below.

- GetConnectionElements Method
- GetDataSetWriterElements Method
- GetPublishedDataSetElements Method
- GetWriterGroupElements Method

Examples

The example below starts at the "root" of the PubSub configuration, and first obtains names of all PubSub connections available (they are at the 1st level). For each PubSub connection, given its name, it obtains names of writer groups configured on that PubSub connection (they are at the 2nd level). And, for each such writer group, given its name, it obtains names of all dataset writers configured on that writer group (they are at the 3rd level). Besides the PubSub object names, the commented parts also show how to obtain more detailed information about each PubSub object.

C#

```
// This example obtains and prints out information about PubSub connections, writer
groups, and dataset writers in the
// OPC UA PubSub configuration.

```

The example below uses the ListAllPublishedDataSetNames Method to retrieve all published dataset from the PubSub configuration. The published datasets are actually organized in the PubSub configuration using a hierarchical structure of dataset folders. The word "all" in the method name denotes that the method will truly return all published datasets in the configuration, not just those at the "root" of the dataset folder structure, or in any specified dataset folder. The method will act recursively in the dataset folder structure, if needed. There are also methods that allow you to work with contents of individual dataset folders. Note that the published dataset names are unique across the PubSub configuration as a whole (regardless of their location in the dataset folder structure), and therefore a published dataset name is sufficient to identify the published dataset, and the dataset folder path is not strictly necessary.

5.1.6 Event Pull Mechanism

In This Topic

Event pull mechanism is an alternative to the traditional delivery mechanism of notifications through event handlers. Setting up event handlers, and properly handling events, is difficult or impossible in some (especially COM-based) tools (e.g. Python) or in some environments (e.g. applications running under Web server). In COM, unless taken care of already by the tool, the developer must also assure that (in an STA model) Windows messages are being pumped by the application.

Note: This feature should only be used when the traditional event delivery approach is not feasible. It is unlikely that you will need to use the event pull mechanism in C# or VB.NET (except maybe for server-side of certain Web apps and Web services).

Event pull mechanism replaces the event handlers by methods that allow the developer to obtain a next available notification from an internally provided queue. Events can then be handled by a loop that calls the “pull” method and processes the notifications. In order to maintain reasonable performance, a so-called long poll approach is used: The method only returns after a notification becomes available, or a specified timeout elapses. Note that the event pull concept is strictly confined to how the OPC Data Client exchanges notifications with the enclosing application, and is not related to how OPC Data Client communicates with OPC servers.

For each event **XXXX**, by convention, two methods for event pull mechanism are provided: A PullXXXX method, which allows to retrieve a single notification, and a PullMultipleXXXX method, which allows to retrieve multiple notifications, if they are available. Although currently is no significant performance difference between the two methods, it is recommended that your code uses the PullMultipleXXXX methods, because it may bring performance benefits in the

future.

The following table shows the traditional events, and their corresponding methods for event pull:

Type	Event	Pull method	PullMultiple method
EasyDAClient	ItemChanged	PullItemChanged	PullMultipleItemChanges
EasyAEClient	Notification	PullNotification	PullMultipleNotifications
EasyUAClient	DataChangeNotification	PullDataChangeNotification	PullMultipleDataChangeNotifications
	EventNotification	PullEventNotification	PullMultipleEventNotifications
	ServerConditionChanged	PullServerConditionChanged	PullMultipleServerConditionChanges
EasyUASubscriber Class	DataSetMessage Event	PullDataSetMessage Method	PullMultipleDataSetMessages Method
	ResolverAccess Event	PullResolverAccess Method	PullMultipleResolverAccesses Method

Each PullXXXX or PullMultipleXXXX method takes an argument that specifies a timeout (in milliseconds). When a notification is available, the methods returns it immediately, and return a non-null object containing the event arguments (or an array of such event arguments, for PullMultipleXXXX). If no notifications are available during the specified period (timeout), the methods returns after the period elapses, but the return value is a null reference.

After your code receives a non-null event arguments object, it can process it as it would do in a traditional event handler.

You will probably be calling the PullXXXX or PullMultipleXXXX method in a loop with some termination condition. Specify a timeout that will allow the loop to react to the termination condition quickly enough. You should not, however, use very low (or zero) timeouts in such a loop, because that would lead to unnecessary high CPU consumption.

In order to use the event pull mechanism, your code needs to set up a queue with a fixed capacity upfront. This is done by setting a corresponding property in the EasyXXClient object. By convention, for an event named **XXXX**, the property name is PullXXXXQueueCapacity. For example, set the EasyUAClient.PullDataChangeNotificationQueueCapacity property to allocate a queue for OPC UA data change notifications.

If you do not set the queue capacity to a positive (non-zero) value, and attempt to use the event pull mechanism, the PullXXXX or PullMultipleXXXX method will throw an InvalidOperationException.

Examples

Examples for OPC Data Access:

C#

```
// This example shows how to subscribe to item changes and obtain the events by pulling
them.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace DocExamples.DataAccess._EasyDAClient
{
    class PullItemChanged
    {
```

```
        public static void Main1()
        {
            // In order to use event pull, you must set a non-zero queue capacity
upfront.
            var client = new EasyDAClient { PullItemChangedQueueCapacity = 1000 };

            Console.WriteLine("Subscribing item changes...");
            client.SubscribeItem("", "OPCLabs.KitServer.2", "Simulation.Random", 1000);

            Console.WriteLine("Processing item changes for 1 minute...");
            int endTick = Environment.TickCount + 60 * 1000;
            do
            {
                EasyDAItemChangedEventArgs eventArgs = client.PullItemChanged(2 *
1000);
                if (eventArgs != null)
                    // Handle the notification event
                    Console.WriteLine(eventArgs);
            } while (Environment.TickCount < endTick);

            Console.WriteLine("Unsubscribing item changes...");
            client.UnsubscribeAllItems();

            Console.WriteLine("Finished.");
        }
    }
}
```

VB.NET

```
' This example shows how to subscribe to item changes and obtain the events by pulling
them.

Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.DataAccess.OperationModel

Namespace DocExamples.DataAccess._EasyDAClient
    Partial Friend Class PullItemChanged
        Public Shared Sub Main1()
            Dim client = New EasyDAClient()
            ' In order to use event pull, you must set a non-zero queue capacity
upfront.
            client.PullItemChangedQueueCapacity = 1000

            Console.WriteLine("Subscribing item changes...")
            client.SubscribeItem("", "OPCLabs.KitServer.2", "Simulation.Random", 1000)

            Console.WriteLine("Processing item changes for 1 minute...")
            Dim endTick As Integer = Environment.TickCount + 60 * 1000
            Do

Examples for OPC UA PubSub:

The example below subscribes to all dataset messages on an OPC-UA PubSub connection with UDP UADP mapping. The connection is specified by its physical parameters, using the scheme name "opc.udp" and the IP address of the multicast group to listen on.

C#

```
// This example shows how to subscribe to all dataset messages on an OPC-UA PubSub
connection, and pull events, and display
// the incoming datasets.
```

```
//
// In order to produce network messages for this example, run the UADemoPublisher tool.
For documentation, see
// http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.

VBScript

```
Rem This example shows how to subscribe to all dataset messages on an OPC-UA PubSub
connection, and pull events, and display
Rem the incoming datasets.
Rem
Rem In order to produce network messages for this example, run the UADemoPublisher
tool. For documentation, see
Rem http://kb.opclabs.com/UADemoPublisher_Basics . In some cases, you may have to
specify the interface name to be used.

Option Explicit

' Define the PubSub connection we will work with.
Dim SubscribeDataSetArguments: Set SubscribeDataSetArguments =
CreateObject("OpcLabs.EasyOpc.UA.PubSub.OperationModel.EasyUASubscribeDataSetArguments")

Dim ConnectionDescriptor: Set ConnectionDescriptor =
SubscribeDataSetArguments.DataSetSubscriptionDescriptor.ConnectionDescriptor
ConnectionDescriptor.ResourceAddress.ResourceDescriptor.UrlString =
"opc.udp://239.0.0.1"
' In some cases you may have to set the interface (network adapter) name that needs to
be used, similarly to
' the statement below. Your actual interface name may differ, of course.
' ConnectionDescriptor.ResourceAddress.InterfaceName = "Ethernet"

' Instantiate the subscriber object.
Dim Subscriber: Set Subscriber =
CreateObject("OpcLabs.EasyOpc.UA.PubSub.EasyUASubscriber")
' In order to use event pull, you must set a non-zero queue capacity upfront.
Subscriber.PullDataSetMessageQueueCapacity = 1000

WScript.Echo "Subscribing..."
Subscriber.SubscribeDataSet SubscribeDataSetArguments

WScript.Echo "Processing dataset message events for 20 seconds..."
Dim endTime: endTime = Now() + 20*(1/24/60/60)
Do
    Dim EventArgs: Set EventArgs = Subscriber.PullDataSetMessage(2*1000)
    If Not (EventArgs Is Nothing) Then
        ' Display the dataset.
        If EventArgs.Succeeded Then
            ' An event with null DataSetData just indicates a successful connection.
            If Not (EventArgs.DataSetData Is Nothing) Then
                WScript.Echo
                WScript.Echo "Dataset data: " & EventArgs.DataSetData
                Dim Pair: For Each Pair in EventArgs.DataSetData.FieldDataDictionary
                    WScript.Echo Pair
                Next
            End If
        Else
            WScript.Echo
            WScript.Echo "*** Failure: " & EventArgs.ErrorMessageBrief
        End If
    End If
Loop While Now() < endTime

WScript.Echo "Unsubscribing..."
Subscriber.UnsubscribeAllDataSets
```

```
WScript.Echo "Waiting for 1 second..."
' Unsubscribe operation is asynchronous, messages may still come for a short while.
WScript.Sleep 1*1000

WScript.Echo "Finished."

' Example output:
'
'Subscribing...
'Processing dataset message events for 20 seconds...

More information

Besides the usual ArgumentException (when your code passes in an improper argument), the InvalidOperationException described above (which also indicates a bug in the code), and system exceptions such OutOfMemoryException, the PullXXXX and PullMultipleXXXX methods can only throw one type of exception, and that is ProcedureCallException. The current implementation does not actually throw this exception type, but future implementations may do so, and we recommend that your code is written in such a way that is ready for that. The ProcedureCallException indicates a failure in the event delivery mechanism (and a likely loss of one or more notifications).

Make sure you always specify a queue capacity that will provide a "buffer" of sufficient length for a difference between the rate of incoming notifications, and the rate your code can consume them. Besides an indication through the event log output (currently in OPC UA only), there is no way to detect queue overflows.

5.1.7 Error Handling

Various kinds of errors may be returned by OPC Data Client, e.g.:

- Errors returned by system calls when performing OPC-related operations.
- In OPC Classic, errors returned by COM/DCOM infrastructure, including RPC errors.
- In OPC UA, errors returned by communication infrastructure, including Web service errors.
- Error returned by OPC-UA Stack or SDK.
- Network-related errors.
- Errors reported by the OPC server you are connecting to.
- Errors detected by the OPC Data Client library.

In general, you cannot reliably prevent all these errors from happening. Many conditions external to your code can cause

OPC failures, e.g. network problems, improper OPC server configuration, etc. For this reason, you should always expect than OPC operation can fail.

OPC Data Client "Classic" and OPC Data Client-UA each define one new type of exception, called OpcException (for OPC "Classic"), or UAException (for OPC-UA), derived from the Exception object. This exception is for all errors arising from OPC operations.

More details about the cause of the problem can be found by interrogating the InnerException property of OpcException or UAException, or by examining the ErrorId property. In most scenarios, however, your code will be handling all OpcException-s or UAException-s in the same way, independent of the inner exception or error code.

The InnerException can be:

- COMException, **especially common in OPC Classic**.
- UAStatusCodeException, when the OPC-UA status code is not as expected.
- UAEngineException, for errors that originates in the OPC-UA engine and not in the OPC service (or OPC-UA SDK).
- UAServiceException, when an OPC-UA defined error occurs.
- LicenseException, if there is a problem with component's license in OPC Data Client-UA.
- An exception from the lower level systems, such as .NET Framework, WCF, OPC-UA stack or SDK.

For more details, see **OPC Classic Errors (Section 5.1.7.3)** or **OPC UA Errors (Section 5.1.7.4)**, respectively.

Because many errors are provided by the infrastructure that OPC Data Client is using, there is no way to provide a comprehensive list of all possible errors. You can, however, be sure that all error will be reported in the way described here, and therefore they can be handled as needed.

If you need to display a meaningful error message to the user, or log it for further diagnostics, it is best to take the OpcException or UAException instance, obtain its base exception using GetBaseException method, and retrieve its Message property. The error message obtained in this way is closest to the actual cause of the problem. OPC Data Client.NET even tries to fill in the error text in cases when the system or OPC server has not provided it.

It should be noted that for OPC Data Client "Classic" and OPC Data Client-UA operations, OpcException or UAException is the ONLY exception class that your code should be explicitly catching when calling OPC Data Client methods or getting properties. This is because you cannot safely influence or predict whether the exception will or will not be thrown. Other kinds of exception, such as those related to argument checking, should NOT be caught by typical application code, because they either indicate a programming bug in your code, or an irrecoverable system problem.

In OPC Data Client-COM, the actual error handling concepts (and related terminology) depend strongly on the programming language and development tool you are using, for example:

- In C++, if you are using the raw interfaces provided by the type library, each function call will return an HRESULT value that you will test using macros such as SUCCEEDED() or FAILED().
- In C++, if you are using "Compiler COM Support" (the #import directive), errors will be converted to exceptions of _com_error type.
- In VBScript, failed function calls will either generate run-time error (with On Error Goto 0), or fill in the Err object with information about the error (with On Error Resume Next).

In COM, OPC Data Client single-operation methods return their success/failure indication using the standard HRESULT and possibly IErrorInfo approaches. This allows you to obtain the error code, and sometimes additional pieces of information such as Description, and Source. The actual type of exception thrown (as discussed above) is hidden using this mechanism. If you need the exception object, use an alternative OPC Data Client method that performs multiple operations at once. Such methods return the success/failure information through the Exception property in the OperationResult (or derived) objects they return, allowing you to obtain the full extent of information associated with the error.

5.1.7.1 Errors and Multiple-Element Operations

Some methods on the main EasyDAClient or EasyUAClient object operate on multiple elements (such as OPC items) at once, and they also return results individually for each of the input elements. Such methods cannot simply throw an exception when there is a problem with processing one of the elements, because throwing an exception would make it impossible to further process other elements that are not causing errors. In addition, exception handling is very slow, and we need some efficient mechanism for dealing with situations when there may be multiple errors occurring at once.

For this reason, methods that work on multiple elements return an array of results, and each result may have an Exception associated with it. If this exception is a null reference, then there has been no error processing the operation on the element, and other data contained in the result object is valid. When the exception is not a null reference, it contains the actual error.

For multiple-element operations, the element-level exceptions are not wrapped in OpcException or UAException, because there is no need for you to distinguish them from other exception types in the catch statement. If there is an exception inside a multiple-level operation, it is always an exception related to OPC operations. The Exception property of the result object in a multiple-element operation therefore contains what would be the InnerException of the OpcException or UAException thrown for a single-element operation.

Exceptions that are not related to OPC operations, such as argument-checking exceptions, are still thrown directly from the multiple-element operations, i.e. they are not returned in the OperationResult object.

5.1.7.2 Errors in Subscriptions

Similarly as with multiple-element operations (above), errors in subscriptions are reported to your code by means of an Exception property in the event arguments passed to your event handler or callback method. If this exception is a null reference, then there has been no error related to the event notification, and other data contained in the event arguments object is valid. When the exception is not a null reference, it contains the actual error.

In event notifications, the exceptions are not wrapped in OpcException or UAException, because there is no need for you to distinguish them from other exception types in the catch statement. If there is an exception related to the event notification, it is always an exception related to OPC operations.

5.1.7.3 OPC Classic Errors

OPC Classic is based on Microsoft COM/DCOM, and as such, the vast majority of exceptions you encounter is of type COMException (or derived from it). The HResult and ErrorId properties of the COMException contain a numeric identification of the problem, which you can use to distinguish between the specific error causes. These exceptions can be

- Errors generated by the target OPC Classic server. It can be a standard error code defined in the OPC specifications, or a custom error code defined by the server vendor.
- Errors from the COM/DCOM infrastructure, either on the computer where the OPC Classic server runs, or on the client computer.
- Errors detected on the client side and generated by OPC Data Client.

In This Topic

A comprehensive list of possible error code cannot be given. Your program must always be ready to handle any error code that it does not explicitly know about. In most cases, you will be treating all errors the same way. In some cases, you

may need to have a special handling for one or a few specific errors.

Some Common Errors

Note: The error texts are for illustration only. They are subject to change without notice. Your program should never rely on the error texts; use the ErrorId, or specific identification properties of various exception types, to distinguish between specific errors.

The addressed OPC Classic Server is not installed

In this case, you will typically receive a COMException "Invalid class string" (localized) with HResult of -2147221005 (0x800401F3), symbolically CO_E_CLASSSTRING. Of course, you will get the same exception if the intended OPC server is actually installed, but you have misspelled its ProgId.

The remote computer cannot be reached

In this case, you will typically receive a COMException "The RPC server is unavailable" (localized) with HResult of -2147023174 (0x800706BA). Of course, you will get the same exception if the intended computer is actually running and accessible, but you have misspelled its name or IP address.

The item you are trying to access does not exist

In this case, you will typically receive a COMException "The item is no longer available in the server address space." (possibly localized) with HResult of -1073479673 (0xC0040007), symbolically OPC_E_UNKNOWNITEMID. Of course, you will get the same exception if the intended item actually exists, but you have misspelled its Item ID. This error is returned by the OPC server if the syntax of the Item ID conforms to the server's requirements, but the item does not exist. If even the syntax of the Item ID is incorrect, you will receive "The item ID does not conform to the server's syntax." (possibly localized) instead, with HResult of -1073479672 (0xC0040008), symbolically OPC_E_INVALIDITEMID.

Reading an item that is not readable, or writing an item that is not writeable

In this case, you will typically receive one of the following COMException-s:

- "Access rights of the topic do not allow reading." with HResult -1073430522 (0xC004C006).
- "Access rights of the topic do not allow writing." with HResult -1073430521 (0xC004C007).

The above exceptions come from the client side, where OPC Data Client is pre-checking the access rights of the item before it actually attempts to perform the operation. If these checks succeed, but the operation is nevertheless rejected by the server, you will typically receive

- "The item's access rights do not allow the operation." (possibly localized) with HResult of -1073479674 (0xC0040006L), symbolically OPC_E_BADRIGHTS.

Bad or Uncertain Quality of the Data

⚠ Except in methods that return the value alone (and not the DAVtq object), bad or uncertain quality is considered a normal operational situation, and does not throw or return an exception. You are responsible for testing the quality (either directly using the Quality Property, or indirectly using the HasValue property) in your code before accessing the Value Property of the DAVtq Class, because in most cases when the quality is bad, the Value is not defined (and is actually a null reference). Uncertain quality usually has some value carried with the data, although its usability is

> questionable. For more information, see **Always test the HasValue property before accessing DAVtq.Value or UAAttributeData.Value (Section 10.5)**.

The methods that do not have data quality in their results, and therefore must return an error instead of the value when the value is not present, include:

- ReadMultipleItemValues
- ReadItemValue

5.1.7.4 OPC UA Errors

Exceptions returned from OPC UA operations of OPC Data Client can be

- Errors generated by the target OPC UA server. It can be a standard error (service result or status code) code defined in the OPC specifications, or a custom error defined by the server vendor.
- Errors from the communication infrastructure, either on the host where the OPC UA server runs, or on the client host, or the components in between.
- Errors detected on the client side and generated by OPC Data Client.

In This Topic

A comprehensive list of possible errors cannot be given. Your program must always be ready to handle any error that it does not explicitly know about. In most cases, you will be treating all errors the same way. In some cases, you may need to have a special handling for one or a few specific errors.

Service Results

OPC UA services indicate the outcome of the operation using *service results*. In OPC Data Client, when the OPC UA server returns a service result that denotes an error, you will receive a UAServiceException. This object contains, among other information, a ServiceResult Property. You can use this property to distinguish between the specific errors. The value it contains is actually of the UAServiceResult type, and is further structured into various fields. In most cases, however, you are only interested in the so-called code bits (an integer) of the status code associated with the service result. The various code bits defined in the OPC UA specifications are available to you as predefined constants in the UACodeBits Class. For example, there is BadNodeIdUnknown Field, BadNotReadable Field, BadNotWritable Field etc. The UAServiceResult Class has an implicit conversion operator to an integer, which returns the code bits of the service result. This means that in order to test the UAServiceException for a specific error, you can simply take its ServiceResult Property, and compare it against the desired constant from the UACodeBits Class.

Some Common Errors

Note: The error texts are for illustration only. They are subject to change without notice. Your program should never rely on the error texts; use the exception type, and possibly other properties of the specific exception types, to distinguish between the errors.

The remote host cannot be reached

The errors in this case vary a lot, depending on factors such as the communication protocol used, or the actual configuration of the target host (when accessible, whether it drops or returns incoming packates that it does not process, etc.). You may receive e.g.:

- A UAServiceException with service result "BadTcpInternalError" (when "opc.tcp" is used).
- A UAServiceException with service result "BadCommunicationError" (when HTTPS is used).
- An EndpointNotFoundException (when HTTP is used).
- A SocketException, when "opc.tcp" is used and the host name is unknown (not found in DNS etc.).

Of course, the true cause of the exception may be that the intended host is actually running and accessible, but you have misspelled its name or IP address.

The addressed OPC UA Server is not installed or not running

The symptoms are in many cases similar as when the remote host cannot be reached.

The node you are trying to access does not exist

In this case, you will typically receive a UAServiceException with service result "BadNodeIdUnknown".

Of course, you will get the same exception if the intended node actually exists, but you have made a mistake in its Node ID.

Reading a node that is not readable, or writing a node that is not writeable

In this case, you will typically receive a UAServiceException with service result "BadNotReadable" or "BadNotWritable".

Bad or Uncertain Status of the Data

> ⚠ Except in methods that return the value alone (and not the UAAttributeData object), bad or uncertain status is considered a normal operational situation, and does not throw or return an exception. You are responsible for testing the status (either directly using the StatusCode Property, or indirectly using the HasValue Property) in your code before accessing the Value Property of the UAAttributeData Class, because in most cases when the status is bad, the Value is not defined (and is actually a null reference). Uncertain status usually has some value carried with the data, although its usability is questionable. For more information, see **Always test the HasValue property before accessing DAVtq.Value or UAAttributeData.Value (Section 10.5)**.

The methods that do not have data quality in their results, and therefore must return an error instead of the value when the value is not present, include:

- ReadMultipleValues
- ReadValue

5.1.8 Callback Queuing

All callbacks (including event notifications) originating from any of the EasyXXClient or EasyXXSubscriber objects are (by default) sent in a queued manner by a dedicated internal thread, improving resiliency against errors in custom code, and decreasing the possibility of deadlocks. When there is a sudden peak in the rate of incoming events, they can accumulate temporarily in the queue, allowing the processing to proceed smoothly.

This callback queuing can be turned on or off by the QueueCallbacks property. Turning off the callback queuing is only advisable in very special circumstances. When the callback queuing is turned off, the callback and event handling is subject to much stricter rules with regard to performance, but also with regard to what the handlers are allowed to do. Most importantly, the handlers must not call any methods on the originating component, because doing so can cause

deadlocks. This rule also applies to calls that may be inflicted by the SynchronizationContext on the component. For example, the common synchronization contexts based on Windows messages (for Windows Forms and WPF) can call other "posted" methods before the action that are instructed to do, causing unpredictable behavior and a possible deadlock too.

> ⚠ For the reasons described above, do not turn the callback queuing off unless you know very well what you are doing.

The capacity of the callback queue is given by the CallbackQueueCapacity property. The memory is not preallocated for the full maximum size, however, and therefore under normal circumstances, there is no penalty for using quite high queue capacities. The callback queue capacity should be large enough to be able to hold all incoming callbacks in case of a sudden "burst", before they are all processed (consumed) by your code.

> ⚠ For errors coming from subscriptions, OPC Data Client uses the same "channel" as for success notifications. For example, in case of the EasyUAClient Class, this means that the errors come through the DataChangeNotification Event or EventNotification Event, and the component treats each monitored item separately. Consequently, in case of an error that affects the whole connection to a particular server (or more servers), callbacks (and/or events) will be generated for every monitored item affected. This is by design. If you are subscribed to larger number of monitored items, this itself can create a "burst" that is way above the normal rate of events. Your code, and the size of the callback queue, need to be prepared for this scenario as well.

If the amount of notifications that needs to be held in the queue exceeds its capacity, a *callback queue overflow* occurs, and these notifications are lost. In addition, a LogEntry Event is generated on the EasyXXClient or EasyXXSubscriber, with corresponding message. If a notification is removed from a queue while it has overflown, the overflow status is cleared, and a different LogEntry Event is generated on the component ("*overflow clearing*"). The event contains *overflow count*, which is effectively the number of notifications that have been lost due to the queue overflow.

The idle time before the internal thread executing the queued callbacks is stopped is controlled by the CallbackQueueIdleTimeToSleep property. The thread is stopped as an optimization measure, to reduce the amount of system resources consumed. When new callbacks come, the thread is automatically started.

5.1.9 Operation Monitoring and Control

The EasyUAClient object provides a ServerConditionChanged event. This event is raised for a change in the condition of an OPC server. Specifically, you receive a notification whenever the connection to the server is established, or whenever the connection is terminated. Whenever there an error (exception) associated with the server condition, it is also available in the event arguments.

The event notification passes to you an EasyUAServerConditionChangedEventArgs object, which contains data about the new server condition. The EndpointDescriptor property identifies the server the notification applies to.
The Boolean Connected property indicates whether the server is now connected. The Exception property contains a null reference in case of no error, or it contains an exception object in case of problems.

Additional properties of the event arguments distinguish the change further. For example, the ConnectionState property contains an enumerated value (ConnectionState Enumeration) with members Disconnected, Connecting, Connected, and Disconnecting. The RetrialDelay property (valid in the Disconnected state) indicates the time (in milliseconds) to the next reconnection attempt.

A corresponding event is not currently available for OPC Classic.

Note that the information provided by this event should be used for oversight, informational and diagnostics purposes only. Specifically, you should not use it to attempt to implement any error recovery mechanism, because error recovery is already built into the OPC Data Client software, and your own mechanism would inevitably cause conflicts.

5.2 Live Mapping Model

Live Mapping works with OPC Data Access ("Classic"), OPC XML-DA and OPC Unified Architecture servers (for data access). Its features include:

- You can map to any OPC item, node attribute or property.
- Different mapping kinds such as Value, Quality, Timestamps, ErrorMessage, and many more.
- Whole class can be mapped at once, or details can be specified on mapped members individually.
- Operations on mapped types can be narrowly targeted as needed using mapping tags.
- Relative OPC browse paths can be used to avoid necessity of mapping to absolute item or node IDs.
- Meta-members allow to relate the mapped object to its location in the address space, and parameters for operations.
- Pre-made node classes for easier mapping.
- Type-less mapping is also possible, for direct correspondence between the .NET members and OPC data.

The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

This functionality is not yet available for OPC UA PubSub.

The live mapping development model allows you to write objects that correspond logically to a functionality provided by whatever is “behind” the OPC data. For example, if part of your application works with a boiler, it is natural for you to create a boiler object in the code. You then describe how your objects and their members correspond to OPC data – this is done using attributes to annotate your objects. Using Live Mapping methods, you then map your objects to OPC data, and perform OPC operations on them.

For example, when you subscribe to OPC items, incoming OPC item changes can directly set corresponding properties in your objects, without any further coding. You can then focus on writing the code that handles these property changes, abstracting away the fact how they come in.

To give a concrete example, here is a piece of code of a .NET object annotated for live mapping with OPC Data Access, in C#:

Live Mapping Annotations

```
[DAType]
class BoilerInputPipe
{
    [DANode]
    public FlowTransmitter FlowTransmitter1 = new FlowTransmitter();

    [DANode]
    public Valve Valve = new Valve();

    [DANode, DAItem]
    public bool InAlarm { get; set; };
}
```

You can use the Liver Mapping model with OPC Data Access, or with OPC Unified Architecture data.

5.2.1 Live Mapping Model for OPC Data (Classic and UA)

The live mapping development model allows you to write objects that correspond logically to a functionality provided by whatever is "behind" the OPC data. For example, if part of your application works with a boiler, it is natural for you to create a boiler object in the code. You then describe how your objects and their members correspond to OPC data – this is done using attributes to annotate your objects. Using Live Mapping methods, you then map your objects to OPC data, and perform OPC operations on them.

For example, when you subscribe to OPC items (in OPC Classic) or OPC attributes (in OPC-UA), incoming OPC notifications about changes can directly set corresponding properties in your objects, without any further coding. You can then focus on writing the code that handles these property changes, abstracting away the fact how they come in.

Note: Some mapping technologies for.NET already exist, from Microsoft or otherwise. These technologies are mainly focused on mapping database information (ORM – Object-relational mapping), and they are not well suitable for automation purposes like OPC. We therefore had to implement a new mapping model. We use the term "live mapping" so that it is clearly distinguished from other mapping technologies used; it also reflects the fact that this kind of mapping is well-suited for real-time, "live" data.

Do not confuse the live mapping model with live binding, also provided by OPC Data Client. The main differences between the two are that

- live mapping is primarily non-visual (both in design and in runtime), and
- live mapping has the ability to work with object types, not just individual members.

With live mapping model, you generally need to do following steps in order:

1. Write classes that are a logical model of your application. If you are following object-oriented principles in your design, chances are that your code already has such classes anyway.
2. Annotate the classes with attributes for live mapping. The main purpose of these attributes is to describe how the members of your classes correspond to nodes in the OPC address space.
3. Create instance(s) of your classes, as usually.
4. Perform the actual mapping, which associates your objects with OPC data.
5. Call mapping operations as needed, e.g. execute OPC reads, writes, or subscribe to changes in OPC values.

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

5.2.1.1 Live Mapping Example

It is best to start with Live Mapping by going through a simple example.

In This Topic

Define the mapping

Our example works with a hypothetical boiler, which is an object composed from other structured objects, such as controllers, a drum, level indicator, and pipes. Some of these objects are composed as well. The precise structure is described in the code comments below.

Note: The code snippets demonstrated here are for OPC Classic. In OPC-UA, the principles of Live Mapping are the same, but the actual attributes and pieces of code are slightly different. If you want to use Live Mapping with OPC-UA, please use the explanation here as a guidance, and refer to the UAConsoleLiveMapping example in the product instead.

The simulated boiler data are provided by the sample OPC server that ships with the OPC Data Client product.

The code below is taken from the ConsoleLiveMapping example that ships with the product (file **Boiler.cs**):

Define Live Mapping

```
using System;
using OpcLabs.BaseLib.LiveMapping;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.LiveMapping;
using OpcLabs.EasyOpc.DataAccess.LiveMapping.Extensions;

namespace ConsoleLiveMapping
{
    // The Boiler and its constituents are described in our application
    // domain terms, the way we want to work with them.
    // Attributes are used to describe the correspondence between our
    // types and members, and OPC nodes.

    // This is how the boiler looks in OPC address space:
    //  - Boiler #1
    //      - CC1001                    (CustomController)
    //          - ControlOut
    //          - Description
    //          - Input1
    //          - Input2
    //          - Input3
    //      - Drum1001                  (BoilerDrum)
    //          - LIX001                (LevelIndicator)
    //              - Output
    //      - FC1001                    (FlowController)
    //          - ControlOut
    //          - Measurement
    //          - SetPoint
    //      - LC1001                    (LevelController)
    //          - ControlOut
    //          - Measurement
    //          - SetPoint
    //      - Pipe1001                  (BoilerInputPipe)
    //          - FTX001                (FlowTransmitter)
```

```
//              - Output
//      - Pipe1002                  (BoilerOutputPipe)
//          - FTX002                (FlowTransmitter)
//              - Output

[DAType]
class Boiler
{
    // Specifying BrowsePath-s here only because we have named the
    // class members differently from OPC node names.

    [DANode(BrowsePath = "Pipe1001")]
    public BoilerInputPipe InputPipe = new BoilerInputPipe();

    [DANode(BrowsePath = "Drum1001")]
    public BoilerDrum Drum = new BoilerDrum();

    [DANode(BrowsePath = "Pipe1002")]
    public BoilerOutputPipe OutputPipe = new BoilerOutputPipe();

    [DANode(BrowsePath = "FC1001")]
    public FlowController FlowController = new FlowController();

    [DANode(BrowsePath = "LC1001")]
    public LevelController LevelController = new LevelController();

    [DANode(BrowsePath = "CC1001")]
    public CustomController CustomController = new CustomController();
}

[DAType]

{
    // Specifying BrowsePath-s here only because we have named the
    // class members differently from OPC node names.

    [DANode(BrowsePath = "FTX001")]
    public FlowTransmitter FlowTransmitter1 = new FlowTransmitter();

    [DANode(BrowsePath = "ValveX001")]
    public Valve Valve = new Valve();
}

[DAType]
class BoilerDrum
{
    // Specifying BrowsePath-s here only because we have named the
    // class members differently from OPC node names.
```

```
        [DANode(BrowsePath = "LIX001")]
        public LevelIndicator LevelIndicator = new LevelIndicator();
    }

    [DAType]
    class BoilerOutputPipe
    {
        // Specifying BrowsePath-s here only because we have named the
        // class members differently from OPC node names.

        [DANode(BrowsePath = "FTX002")]
        public FlowTransmitter FlowTransmitter2 = new FlowTransmitter();
    }

    [DAType]
    class FlowController : GenericController
    {
    }

    [DAType]
    class LevelController : GenericController
    {
    }

    [DAType]
    class CustomController
    {
        [DANode, DAItem]
        public double Input1 { get; set; }

        [DANode, DAItem]
        public double Input2 { get; set; }

        [DANode, DAItem]
        public double Input3 { get; set; }

        [DANode, DAItem(Operations = DAItemMappingOperations.ReadAndSubscribe)] // no
OPC writing
        public double ControlOut { get; set; }

        [DANode, DAItem]
        public string Description { get; set; }
    }

    [DAType]
    class FlowTransmitter : GenericSensor
    {
```

```
    }

    [DAType]
    class Valve : GenericActuator
    {
    }

    [DAType]
    class LevelIndicator : GenericSensor
    {
    }

    [DAType]
    class GenericController
    {
        [DANode, DAItem(Operations = DAItemMappingOperations.ReadAndSubscribe)] // no
OPC writing
        public double Measurement { get; set; }

        [DANode, DAItem]
        public double SetPoint { get; set; }

        [DANode, DAItem(Operations =
            DAItemMappingOperations.ReadAndSubscribe)] // no OPC writing
        public double ControlOut { get; set; }
    }

    [DAType]
    class GenericSensor
    {
        // Meta-members are filled in by information collected during
        // mapping, and allow access to it later from your code.
        // Alternatively, you can derive your class from DAMappedNode,
        // which will bring in many meta-members automatically.
        [MetaMember("NodeDescriptor")]
        public DANodeDescriptor NodeDescriptor { get; set; }

        [DANode, DAItem(Operations = DAItemMappingOperations.ReadAndSubscribe)] // no
OPC writing
        public double Output
        {
            get { return _output; }
            set
            {
                _output = value;
                Console.WriteLine("Sensor \"{0}\" output is now {1}.", NodeDescriptor,
value);
            }
```

```
        }

        private double _output;
    }

    [DAType]
    class GenericActuator
    {
        [DANode, DAItem]
        public double Input { get; set; }
    }
}
```

Notice the setter for the GenericSensor.Output property in the code above. It contains your application logic for "what to do when sensor's output changes" (in our example, we simply display the sensor's identification and the new value). Similarly, you can write logic that handles other OPC item changes, or – in the opposite direction – provides values to be written to the OPC items.

Perform operations

Let us now use the above mapping definitions to actually perform some meaningful tasks.

First, we create an instance of our logical "boiler" object, and using the DAClientMapper object (for mapping to OPC Data Access), we map it to OPC. The type mapping definition for the Boiler does not contain information about which OPC server to use, and where in its address space (tree of items) can the boiler items be found. This is intentional - although such information could have been specified directly on the Boiler class, it would hamper the reusability of such class. We therefore provide that information at the moment of mapping, by specifying it inside the new DAMappingContext passed to the mapper. Similarly, we specify the requested update rate.

The code pieces below are taken from the ConsoleLiveMapping example that ships with the product (file **Program.cs**).

Perform Live Mapping

```
varboiler1 = new Boiler();
varmapper = new DAClientMapper();
mapper.Map(boiler1, new DAMappingContext
    {
        ServerDescriptor = "OPCLabs.KitServer.2",   // local OPC server
        // The NodeDescriptor below determines where in the OPC address
        // space we want to map our data to.
        NodeDescriptor = new DANodeDescriptor
            { BrowsePath = "/Boilers/Boiler #1" },
        // Requested update rate (for subscriptions):
        GroupParameters = 1000,
    });
```

With the mapping already in place, we can easily do various operations on the mapped objects. For example, we can read in all data of the boiler, and the values will appear directly in the properties of our Boiler object:

Read data with Live Mapping

```
    Console.WriteLine();
    Console.WriteLine("Reading all data of the boiler...");
    mapper.Read();
    Console.WriteLine("Drum level is: {0}",
        boiler1.Drum.LevelIndicator.Output);
```

You can also modify properties of the level controller, e.g. change its setpoint by setting the SetPoint property, and then send all writeable values to level controller through OPC:

Write data with Live Mapping

```
    Console.WriteLine();
    Console.WriteLine("Writing new setpoint value...");
    boiler1.LevelController.SetPoint = 50.0;
    mapper.WriteTarget(boiler1.LevelController, /*recurse:*/false);
```

If you want to subscribe to changes occurring in the boiler, and have the properties in your object automatically updates with new values, you can do it as below. When, e.g., an output of any sensor changes, the Output property will be set on the corresponding object, and the code that (in our example) displays the new value will run.

Subscribe to data with Live Mapping

```
    Console.WriteLine();
    Console.WriteLine("Subscribing to boiler data changes...");
    mapper.Subscribe(/*active:*/true);

    Thread.Sleep(30 * 1000);

    Console.WriteLine();
    Console.WriteLine("Unsubscribing from boiler data changes...");
    mapper.Subscribe(/*active:*/false);
```

Benefits

You can already see some of the benefits of the live mapping in this simple example. The code that you write can focus on the logic of the application, and works directly with members of your .NET objects. You do not have to clutter your code with OPC-specific information such as server and item IDs. It also gets very easy to reuse the mapped types: If you had more boilers that are represented identically in the OPC address space, you can simply create more Boiler objects and map them all, without a need to change anything in the definition of the Boiler class.

5.2.1.2 Live Mapping Overview

In live mapping model, you end up creating Mappings that relate Mapping Sources with Mapping Targets. These concepts are explained further below.

The live mapping is orchestrated by the mapper object, described in a separate chapter (see The Mapper Object).

5.2.1.2.1 Mapping Sources

The mapping source is a data provider and/or consumer external to your application code.

For OPC Data Access, there are two types of mapping sources that you can use:

- The DAClientItemSource represents an OPC item.
- The DAClientPropertySource represents an OPC property.

For OPC Unified Architecture, following type of mapping source exists:

- The UAClientDataMappingSource represents an attribute of an OPC-UA node.

One mapping source can be (and often is) shared by multiple mappings. This happens e.g. when you map multiple members to the same source, using different Mapping Kinds (for example, you may map separate members to the value, timestamp, and quality information of the OPC item).

When you use the attributes to define the live mappings, mapping source objects are created and maintained together with their Mappings, so normally you do not deal with them directly.

5.2.1.2.2 Mapping Targets

The mapping target is an element in your code from which data can be obtained or that can accept data. Most typically, it is a property of your object, but it can also be a field, method, or an event.

The actual mapping target is represented by the ObjectMemberLinkingTarget class. When you use the attributes to define the live mappings, mapping target objects are created and maintained together with their Mappings, so normally you do not deal with them directly.

5.2.1.2.3 Mappings

The mapping is a relation between a mapping source and a mapping target. Besides specifying which mapping source and mapping target belong together, it also specifies how and when the data is being transferred between the two.

For example, a mapping for OPC Data Access items (DAClientItemMapping) may specify that the data is only transferred (from the source to the target) when a “Read” operation is requested (see Mapping Operations) and that the data will be in form of the value-timestamp-quality triple, i.e. a DAVtq object (see Mapping Kinds). With OPC-UA and UAClientDataMapping, the “Read” operation exists as well, and an example form of transfer may be the UAAttributeData, which contains the attribute value, status code, and timestamps. Or, the transferred data may simple be the OPC value itself.

When you annotate your objects using attributes, and then map your objects using the mapper object, the necessary mappings are created for all members of your objects that are annotated in such way. You therefore do not normally need to create mappings individually.

For OPC Data Access, there are two types of mappings that you can use:

- The DAClientItemMapping relates a DAClientItemSource to some mapping target. It refers to an OPC item, and you can read it or write it, or subscribe to it. These mappings are created with the use of the DAItem attribute (see further below).
- The DAClientPropertyMapping relates a DAClientPropertySource to some mapping target. It refers to an OPC property, and you can get its value. These mappings are created with the use of the DAProperty attribute (see

further below).

For OPC Unified Architecture, following type of mapping exists:

- The UAClientDataMapping relates a UAClientDataMappingSource to some mapping target. It refers to an attribute of an OPC-UA node , and you can read it or write it, or subscribe to it. These mappings are created with the use of the UAData attribute (see further below).

5.2.1.3 Attributes for Live Mapping

By annotating your types and members by attributes, you provide information to the live mapping system about the correspondences between the source OPC system and the target .NET objects.

For example, using the combination of DANode and DAItem attributes on a property of your object, you denote that the property corresponds to a node in OPC-DA address space, specify the name of that node (if different from property name), and mark the node as OPC item, i.e. capable of reading, writing or subscriptions. Using other attributes, you can also specify parameters for these mapping operations (such as the requested update rate). In OPC-UA, you would use a similar combination of UANode and UAData attributes.

Attributes in .NET are classes that, by convention, are named so that they end in the word "**Attribute**". Some languages, such as C#, allow you to omit the final **Attribute** word, when the attribute is specified. For example, in C#, you can write [DAItem] instead of [DAItemAttribute]. In this document, we will mostly use the "shortened" named of attribute classes. Remember that in some languages, you may have to use the full name of the attribute class, and therefore append the word "**Attribute**" to the attribute name listed here.

The following table shows the Live Mapping attributes common for OPC Classic and OPC-UA, and the type of elements they can be applied to.

Attribute	Purpose	on Class or Struct	on Property, Method, or Field	on Event
MappingTag	Member mapping		✔	✔
MetaMember	Member mapping		✔	

The following table shows the attributes available for OPC Classic, and the type of elements they can be applied to.

Attribute	Purpose	on Class or Struct	on Property, Method, or Field	on Event
DAItem	Member mapping		✔	✔
DAItemIdTemplate	Propagated parameter	✔		
DAMember	Member mapping		✔	
DANode	Member mapping		✔	✔
DAProperty	Member mapping		✔	
DARead	Propagated parameter	✔	✔	✔
DASubscription	Propagated	✔	✔	✔

Attribute	Purpose	on Class or Struct	on Property, Method, or Field	on Event
	parameter			
DAType	Type mapping	✔		
Server	Propagated parameter		✔	✔

The following table shows the attributes available for OPC Unified Architecture, and the type of elements they can be applied to.

Attribute	Purpose	on Class or Struct	on Property, Method, or Field	on Event
UAData	Member mapping		✔	✔
UADataChangeFilter	Propagated parameter	✔	✔	✔
UAEndpoint	Propagated parameter		✔	✔
UAMember	Member mapping		✔	
UAMonitoring	Propagated parameter	✔	✔	✔
UANamespace	Propagated parameter	✔		
UANode	Member mapping		✔	✔
UANodeIdTemplate	Propagated parameter	✔		
UARead	Propagated parameter	✔	✔	✔
UASubscription	Propagated parameter	✔	✔	✔
UAType	Type mapping	✔		

The meaning of these attributes will be explained in subsequent chapters, and can be found in the reference documentation as well.

5.2.1.4 Propagated Parameters

Attributes that are marked with “propagated parameter” in the above table do not create a new type definition or member mapping. Instead, when used, they establish or change parameter values that will be used when the actual mapping is created, using attributes for Type Mapping or Member Mapping.

The parameters set in this way also propagate further down in the mapping hierarchy. E.g. if you put a propagated

parameter attribute on a type, it will apply to that type and all its mapped members, and if any such member refer to a mapped type, the parameters will propagate recursively to it. If, however, any of these down-level types or members is annotated with the same attribute, the values from this new attribute will replace the parameters that were set higher in the hierarchy.

5.2.1.5 Type Mapping

Types involved in the live mapping for OPC Data need to be annotated with the DAType attribute (OPC Classic) or the UAType attribute (OPC-UA). If you derive your types from one of the Mapped Node Classes (such as DAMappedNode or UAMappedNode), this attribute is inherited and you do not have to explicitly specify it again.

Both reference and value types are allowed in the live mapping.

In addition to the DAType (or UAType) attribute, you can use other ("propagated parameter") attributes on your type, as seen from the table in the Attributes for Live Mapping chapter. These additional attributes do not have direct effect on the type itself, but influence all members of that type. For example, if you specify the DASubscription attribute on your type, and specify the requested update rate, this update rate will be used with all members of that type, unless overridden again by the DASubscription attribute on any member. Similarly, in OPC Unified Architecture, use can specify the sampling interval using the UAMonitoring attribute, and it will be propagated further down.

5.2.1.6 Member Mapping

The member mapping has its specifics depending whether you apply the mapping attribute to a property or field (which is most common), to a method, or to an event. In the following three chapters, we will explain the mapping behavior with these different types of members.

The subsequent chapters then explain how the actual mappings are created with different attributes, and what is their meaning and usage.

5.2.1.6.1 Mapping Property and Field Members

This is the most obvious and straightforward member mapping. The property's or field's value is the actual mapped data.

The property or field type must be compatible with the type of data, as given by the mapping (see Mapping Kinds for details on types for different kinds of mappings). Note that it is generally preferred to use properties rather than fields for the mapping purposes.

Indexed properties and fields are not currently supported. I.e. you can have an array contained in the mapped property or field, but the array has to be treated as a whole.

5.2.1.6.2 Mapping Method Members

When you map a method, it has to conform to one of the following:

- A method (function) that has no arguments, and returns a value. This method can be used to obtain values from the target. It is equivalent to a property getter.
- A method that has one argument (return value is ignored and can be void). This method can be used to modify values in the target. It is equivalent to a property setter.

The method return type (in first case), or the method's argument type (in second case) must be compatible with the type

of data, as given by the mapping (see Mapping Kinds for details on types for different kinds of mappings).

5.2.1.6.3 Mapping Event Members

An event can only serve for delivering data from the source to the target. When you map an event, the event handler has to accept two arguments. The first argument is the sender – the target object itself. The second argument contains the mapped data, and is of type TargetDataEventArgs<TData> (if the target type is not known) or TargetDataEventArgs<TData,TTarget> (for target of type TTarget).

TData is the type of data, as given by the mapping (see Mapping Kinds for details on types for different kinds of mappings).

5.2.1.6.4 Map-through, OPC Nodes and OPC Data

Following attributes are used to create or describe the actual member mappings for OPC Classic (Data Access):

- DAMember: Causes the mapping to continue into the value of the mapped member (map-through).
- DANode: Marks the member that represents a node in the OPC-DA address space (no new mapping is directly created just by using this attribute), and maps through it.
- DAItem: Gives information about OPC Data Access item, and creates a mapping for it.
- DAProperty: Gives information about OPC Data Access property, and creates a mapping for it.

Following attributes are used to create or describe the actual member mappings for data with OPC Unified Architecture (OPC-UA):

- UAMember: Causes the mapping to continue into the value of the mapped member (map-through).
- UANode: Marks the member that represents a node in the OPC-UA address space (no new mapping is directly created just by using this attribute), and maps through it.
- UAData: Gives information about OPC-UA data provided by an attribute on an OPC-UA node, and creates a mapping for it.

In order to describe what precisely happens when these attributes and their combinations are used, it is important do understand that when the mapping is done, there is a "current" OPC node maintained by the mapper object, and a "current" object being mapped. When the mapping is started, the current OPC node is given to the mapper (or, if omitted, starts at the root of the address space), and the current object is the object to be mapped, also passed to the mapper.

As the mapping progresses, the current OPC node is only changed by the DANode (or UANode) attribute. That is, if you want any of your members be mapped to a node different from the parent node, you need to annotate that member with the DANode (or UANode) attribute. The current OPC node is thus changed for that member and anything below it in the mapping hierarchy.

The DAMember and DANode (or the UAMember and UANode) attributes both function as map-through. This means that when they are encountered during mapping, the value of the annotated member is obtained, and the mapping continues into the object given by the value (if the value is a null reference, it is simply ignored). You can therefore have a structure of objects where object's properties or fields contain other objects, and the whole structure can be mapped at once.

The difference between the DAMember and DANode (or UAMember and UANode) is that with DAMember (UAMember), the current OPC node is not changed. This means that members of the child object will be mapped to the same OPC node as the parent object. With DANode (UANode), however, the members of the child object will be mapped to an OPC node different from the parent. Which node precisely is used for the child object's members is described in a subsequent chapter, Browse Path and Node Id Resolution. Here, it is enough to say that if you don't specify any argument to the DANode (UANode) attribute, the current OPC node will be changed to a node with the same name as the member you

are annotating. So, if your property is named e.g. Output, it will correspond to an **Output** node in the OPC address space.

The DAMember and DANode (or UAMember and UANode) attributes do not create any OPC data mappings that can actually have some effect on the underlying OPC system. They are just helper attributes that allow you to define the structure of mappings. In order to create OPC data mappings, you need to annotate your member with either DAItem or DAProperty attribute (in OPC Classic), or with the UAData attribute (in OPC-UA).

With the DAItem attribute, you specify that the annotated member should be mapped to an OPC Data Access item, and you optionally provide additional information about how the mapping should be done. The arguments that you can use with the DAItem attribute allow you to optionally specify:

- AccessPath: An optional data path suggestion to the server.
- RequestedDataType: The data type requested (VarTypes.Empty for the server's canonical data type).
- Kind: Specifies how the item will be mapped (see Mapping Kinds).
- Operations: The item mapping operations in which the mapping will participate (see Mapping Operations).
- ItemType: The type of OPC item.

Note that with the DAItem attribute, you do not specify information about which OPC node (item) should be mapped: This information comes from the usage of DANode attribute(s).

With the DAProperty attribute, you specify that the annotated member should be mapped to an OPC Data Access property (on an item), specify the numerical ID of the property, and optionally additional information about how the mapping should be done.

With the UAData attribute, you specify that the annotated member should be mapped to an OPC-UA attribute, and you optionally provide additional information about how the mapping should be done. The arguments that you can use with the UAData attribute allow you to optionally specify:

- AttributeId: Identifies an attribute of a node.
- ValueType: The type of the OPC-UA Value attribute.
- IndexRangeList: List of index ranges for individual array dimensions.
- Kind: Specifies how the item will be mapped (see 7.1.9Mapping Kinds).
- Operations: The item mapping operations in which the mapping will participate (see 7.1.8Mapping Operations).

Note that with the UAData attribute, you do not specify information about which OPC-UA node should be mapped: This information comes from the usage of UANode attribute(s).

Typically, when the structure of your objects follows the structure of the OPC address space, you will annotate object members as follows:

- Members that correspond to OPC branches (folders): In OPC Classic, use the DANode attribute. In OPC-UA, use the UANode attribute.
- Members that correspond to OPC leaves (items, variables): In OPC Classic, use the DANode and DAItem attributes together. In OPC-UA, use the UANode and UAData attributes together.

It is, however, perfectly possibly (and indeed, practical) that your objects may have a structure that differs from a structure of the OPC address space – either just at some places, or globally. In such case, you can still make your objects "fit" the address space, by proper placing of all attributes described here.

5.2.1.6.5 Browse Path and Node Id Resolution

Items in OPC Data Access are ultimately identified by their item IDs (node IDs), which are strings defined by the server. Their syntax is not standardized, and although they commonly look like a sequence of names or numbers with some separators interspersed (such as "Boiler.Drum1001.LIX001.Output"), there is no general way to construct the item IDs

without browsing the OPC server's address space.

In OPC-UA, nodes have their Node Ids, which are a bit more complex (they are qualified by a namespace, and can be of several types, not just strings) – but effectively, they behave similarly. Their values are not generally standardized; they are completely determined by the concrete OPC-UA server you are connecting to.

When mapping, you could specify the precise node ID with the DANode (or UANode) attribute. This may work in some scenarios, but has severe limitations. The OPC address space (and your object structure) typically contains repeated patterns of nodes that are just placed differently. You want to define and map object types that match these patterns, but because the OPC node IDs will differ based on the placement of the pattern in the OPC address space, you won't be able to tell a unique item ID for each member.

This problem can be solved by using browse paths – sequences of item names that start from a known place in the OPC address space (e.g. in its root). The names in browse paths are "short" names that are used when browsing and sometimes displayed to the user, and the "short" node name typically remains the same if the node with the same meaning (a part of node pattern) is placed differently in the OPC address space. The mapping can translate the browse paths to item IDs when they are actually needed. For more on browse paths, see 4.11.7Browse Paths.

In order to specify nodes using a browse path, use the BrowsePath argument of the DANode (or UANode) attribute. It is a string that can contain an absolute or relative browse path. An absolute browse path string has similar limitations as the item ID; you may find it useful to define the starting point for the mapping (always needed in OPC-UA), or if the mapping does not start at the root of the OPC address space (in OPC Classic), though.

With a relative browse path string, you can specify that the member annotated with DANode (or UANode) attribute will belong to an OPC node that is based on the current OPC node, but appended with the relative browse path given. The relative browse path string can contain a single "short" item name, or multiple separated names forming a longer path.

For example, if the current OPC node (for the parent) in OPC Classic is given by browse path '/Boiler/Drum1001/LIX001', and your member is annotated with DANode attribute with BrowsePath = "Output", the OPC node for the member will be given by a browse path '/Boiler/Drum1001/LIX001/Output', which can then be translated to a full item ID. When the same type containing your member is used within a different context (at different place in the OPC address space), the resulting browse path will be different, but still contain "Output" node at the end. This is how repeated node patterns can be mapped without having to specify the individual item IDs.

By default, when the DANode (or UANode) attribute is used without further arguments, the name of the member being annotated is used as the relative browse path string for the DANode (or UANode) attribute. This means that if you name your members the same as the nodes in the OPC address space, you do not have to provide any additional arguments to the DANode (or UANode) attribute. This is a common practice, but if some members cannot follow it, you can still specify a different browse path just for them.

In some cases, the use of browse paths is not possible or practical, but you can define a "rule" specifying how the node IDs are constructed for the concrete OPC server and concrete part of its address space. In such case, you can use the DAItemIdTemplate (or UANodeIdTemplate) attribute to annotate your type, giving it an ItemIdTemplateString (or a NodeIdTemplateString, in OPC-UA) argument that specifies how a node ID of a node is made of the parent node Id, and browse name of the node being mapped (a member name, typically).

Following macros can be used in template strings for DAItemIdTemplate attribute:

- **$(ParentItemID)**: The OPC Item Id of the parent node.
- **$(ParentNodePath)**: The OPC node path of the parent node (only in OPC XML-DA).
- **$(BrowseName)**: The browse name of current node.

Following macros can be used in template strings for UANodeIdTemplate attribute:

- **$(ParentNodeID)**: The node Id of the parent OPC-UA node.
- **$(BrowseName)**: The browse name of current node.

Final note: In OPC Classic, it is possible to specify combinations of BrowsePath and ItemId arguments of the DANode attribute, and further combine it with the DAItemIdTemplate attribute. In OPC-UA, it is possible to specify combinations of BrowsePath and NodeId arguments of the UANode attribute, and further combine it with the UANodeIdTemplate attribute.

In such cases, the information specified at the "deepest" level prevails. If both the browse path and node ID are specified for a node, then both are passed to the underlying OPC client object for processing. Which one of them will be finally used depends on many factors, including the concrete capabilities of the server and the version(s) of OPC specifications it conforms to, so in such case, you are responsible for guaranteeing that both the browse path and the item ID represent the same node.

5.2.1.6.6 Meta- Members

Sometimes you may have a need to obtain additional information that comes from the mapping process; such as what were the resulting values of propagated parameters, or what is the precise node the current object is being mapped to (this is useful when the object is used repeatedly for patterns of nodes in the OPC address space). In order to have this information stored into members of your objects, you can use *meta-members*.

Annotating a member (field, method or property) with the MetaMember attribute causes it to be set to named information gathered during mapping (a meta-information).

The MetaMember attribute has a Name argument that denotes which meta-information will be used.

Meta-members in the following table are available for both OPC Classic and OPC-UA:

Name	Type	Description
Mappings	IEnumerable<AbstractMapping>	An enumeration of mappings defined directly on the target object.
Parent	Object	A reference to the parent target object; **null** if none.

In addition, meta-members in the following table are available for OPC Classic:

Name	Type	Description
GroupParameters	DAGroupParameters	An object containing subscription parameters, such as the requested update rate.
NodeDescriptor	DANodeDescriptor	The descriptor of the OPC node involved in the operation.
ReadParameters	DAReadParameters	The read parameters (such as data source or value age).
ServerDescriptor	ServerDescriptor	An OPC server involved in the operation.

In addition, meta-members in the following table are available for OPC-UA:

Name	Type	Description
EndpointDescriptor	UAEndpointDescriptor	An OPC-UA server involved in the operation.
MonitoringParameters	UAMonitoringParameters	An object containing monitoring parameters, such as the sampling interval.
NodeDescriptor	UANodeDescriptor	The descriptor of the OPC-UA node involved in the operation.
ReadParameters	UAReadParameters	The read parameters (such as the maximum age of the value).
SubscriptionParameters	UASubscriptionParameters	An object containing subscription parameters, such as the publishing interval.

All meta-information is constant after being established, and changing it later has no effect on the underlying mappings.

5.2.1.6.7 Mapping Tags

Mapped members can be tagged with one or more tags. When performing operations, the developer can specify that only members with certain tag, or combination of tags, will be affected.

A mapping tag is any non-empty string.

In order to place a mapping tag on any mapped member, use the MappingTag attribute with it. You can repeat the MappingTag attribute on the member, if you wish the member be tagged with multiple tags.

If you are creating library objects that can be shared with other projects or developers, you are responsible for making sure that the same tag is not accidentally used for different purposes. It is therefore recommended to design a scheme that prevents such conflicts. For example, you may use a namespace approach, and have tags such as "MyCompany.MyProduct.MyComponent.MyTag".

5.2.1.6.8 Deferred Mapping

With deferred mapping, the mapped node object does not have to exist at the time of mapping, but is determined later, when it is actually needed. This is useful e.g. if it is costly to create the full object graph upfront, either because it is very large, or because it depends on dynamic factors that are not known at the time of mapping.

In order to use deferred mapping, you need to:

1. Specify Deferred = true with the DANode or UANode attribute. This causes the mapped member be set to a function ("deferred mapping function") that returns the mapped object (normally, the mapped member contains the mapped object itself).
2. Set the DeferredMapNodeFunction of the DAClientMapper or UAClientMapper to a function that returns the deferred mapping function (see above) for a given mapping context.

The deferred mapping is used in OPC-UA Modelling to dynamically provide node objects whose types depend on the information model of the OPC-UA server.

5.2.1.7 Mapped Node Classes

The DAMappedNode class is a pre-made base class for mapping OPC Data Access nodes. The UAMappedNode class is a pre-made base class for mapping OPC-UA data nodes.

You may (but do not have to) use this class as a base class for your objects that you map to OPC Data Access (or OPC-UA data) nodes. The class is already annotated with the DAType (or UAType) attribute, and contains properties that are mapped to useful meta-members, such as the NodeDescriptor property.

Sometimes it is not possible to use these mapped node classes, usually because you already have a class hierarchy where your objects are derived form a different base that you cannot change. In other cases, however, the DAMappedNode (or UAMappedNode) class serves as a handy shortcut that can make your code shorter.

5.2.1.8 Mapping Operations

There are several things you can do with OPC Data: you can read from them, write to them, or subscribe to their changes. Not all mappings should be involved in all operations, and you therefore need to specify the operations that are of interest to you.

For DAClientItemMapping (OPC Data Access items), doing this means properly setting the Operations argument of the DAItem attribute. You can set it to one of the following values, or their combination:

- DAItemMappingOperations.Read: A Read operation.
- DAItemMappingOperations.Write: A Write operation.
- DAItemMappingOperations.Subscribe: A Subscribe operation.

If you want a combination, you can use a logical OR of the individual values, or use a predefined symbolic name such as ReadAndWrite, ReadAndSubscribe, etc. By default, the Operations argument is set to DAItemMappingOperations.All, meaning that the mapping will be involved in all operations.

There is just one mapping operation for DAClientPropertyMapping (OPC Data Access properties) – the "Get" operation that obtains the value of the OPC property. For OPC-DA property mappings, it is therefore neither necessary nor possible to specify the operation(s) that certain mapping should be involved in.

For UAClientDataMapping (in OPC-UA), you specify the operations by properly setting the Operations argument of the UAData attribute. You can set it to one of the following values, or their combination:

- UADataMappingOperations.Read: A Read operation.
- UADataMappingOperations.Write: A Write operation.
- UADataMappingOperations.Subscribe: A Subscribe operation.

The operations do not get actually executed until you write and run a code that does it. See Invoking the Operations for details.

5.2.1.9 Mapping Kinds

When you describe that certain mapping target (e.g. a property) should be mapped to certain mapping source (e.g. an OPC item), there is still a piece of information missing: What exactly is the content of that mapping target? For example, with OPC-DA item, does the mapped element contain the value of the OPC item itself, or the quality, or does it contain the value/timestamp/quality combination, or even something else?

In order to distinguish between these, the live mapping has a concept of a mapping kind. You can choose which kind of

mapping to use for certain mapping target. You can also map the same source to multiple targets, each time with a different mapping kind. Using this approach, you can e.g. map the value, timestamp, and quality, each to a separate property.

The mapping kind is specified using the Kind property of the DAItem attribute (for OPC-DA item mappings) on the target member or on the UAData attribute (OPC OPC-UA data mappings).

The following table lists all possible mapping for OPC-DA item mappings. When no mapping kind is specified, the default mapping kind of Value is used.

Kind	Type	Description
Result	OperationResult or a derived type	Map the operation result.
ErrorId	Int32	Map the error ID. Always empty with success.
Exception	Exception or a derived type	Map the exception. null if the operation has been successful.
ErrorMessage	String	Map the error message. An empty string if the operation has been successful.
StatusInfo	StatusInfo	Map the status information.
Vtq	DAVtq or DAVtq<*T*>	Map the item value/timestamp/quality combination. See Note 1.
Value	Object or *T*	Map the item value. This is the default mapping kind. See Note 1.
Timestamp	DateTime	Map the timestamp. In UTC. See Note 1.
TimestampLocal	DateTime	Map the timestamp. In local time. See Note 1.
Quality	DAQuality	Map the OPC quality. See Note 1.

For OPC-DA property mappings, the mapping kind is specified using the Kind property of the DAProperty attribute on the target member. The following table lists all possible mapping for OPC-DA property mappings. When no mapping kind is specified, the default mapping kind of Value is used.

Kind	Type	Description
Result	OperationResult or a derived type	Map the operation result.
ErrorId	Int32	Map the error ID. Always empty with success.
Exception	Exception or a derived type	Map the exception. null if the operation has been successful.
ErrorMessage	String	Map the error message. An empty string if the operation has been successful.
StatusInfo	StatusInfo	Map the status information.
Value	Object or *T*	Map the property value. This is the default mapping kind. See Note 1.

The following table lists all possible mapping for OPC-UA data mappings. When no mapping kind is specified, the default mapping kind of Value is used.

Kind	Type	Description
Result	OperationResult or a derived type	Map the operation result.
ErrorId	Int32	Map the error ID. Always empty with success.
Exception	Exception or a derived type	Map the exception. null if the operation has been successful.
ErrorMessage	String	Map the error message. An empty string if the operation has been successful.
StatusInfo	StatusInfo	Map the status information.
AttributeData	UAAttributeData or UAAttributeData <*T*>	Map the attribute value/source timestamp/server timestamp/status code combination. See Note 1.
Value	Object or *T*	Map the item value. This is the default mapping kind. See Note 1.
ServerTimestamp	DateTime	Map the server timestamp. In UTC. See Note 1.
ServerTimestampLocal	DateTime	Map the server timestamp. In local time. See Note 1.
SourceTimestamp	DateTime	Map the source timestamp. In UTC. See Note 1.
SourceTimestampLocal	DateTime	Map the source timestamp. In local time. See Note 1.
StatusCode	UAStatusCode	Map the status code. See Note 1.

Note 1: The mapping target value is not changed if the operation resulted in an exception. This means that when an error occurs, the mapping target with this mapping kind will not be reset to null or other default value; in fact it won't be influenced at all. E.g. if an item's value (a property annotated with mapping kind of Value) is successfully obtained once, and then an error occurs in a subsequent operation, the target property will remain unchanged. You can detect the error by additional mappings with different mapping kinds (e.g. Exception).

5.2.1.10 Mapping Arguments and Phases

✔p>When a mapping operation, such as Read, Write is performed, the execution is made in certain phases. First, the arguments for the operation are obtained from the targets, the actual operation then takes places, and after that, the results are stored to the targets again. For operations such as Subscribe, when the mapping source generates an asynchronous event, similar phases exist during the processing of the notification as well.

For the purpose of clarity, we will call the individual phases as follows:

- **Input**: Before the mapping operation is executed, values are obtained from the mapping target (and then send to the mapping source).
- **Output**: After the mapping operation has been executed, values (received from the mapping source) are stored to the mapping target.
- **Notification Input**: When an asynchronous notification arrives from the mapping source, the values contained in the notification are stored to the mapping target.
- **Notification Output**: When an asynchronous notification from the mapping source is finalized, it is updated with the values obtained from the mapping target. Not currently used.

You can map some of Outputs and Notification Inputs, or none, or all of them – all these approaches are valid, because it is up to you how you handle the data that comes from the mapping source. With Inputs (and Notification Outputs), you must, however, obey the rules that exist for every mapping operation, and map the proper combination of them, so that the mapping source can receive the data it expects.

The following table shows how (depending on the item mapping kind) the Read, Write and Subscribe operations treat their mapping arguments for OPC-DA item mappings.

	Mapping Operation		
Mapping Kind	**Read**	**Write**	**Subscribe**
Result	Output	Output	Notification Input
ErrorId	Output	Output	Notification Input
Exception	Output	Output	Notification Input
ErrorMessage	Output	Output	Notification Input
StatusInfo	Output	Output	Notification Input
Vtq	Output	Input	Notification Input
Value	Output	Input	Notification Input
Timestamp	Output	Input	Notification Input
TimestampLocal	Output	Input	Notification Input
Quality	Output	Input	Notification Input

The Write operation in OPC-DA can either write just a value, or a value/timestamp/quality triple. Only following combinations of inputs are therefore valid for the OPC-DA Write operation:

Vtq	Value	Timestamp or TimestampLocal	Quality	Outcome
✔				Value/timestamp/quality triple is written.
	✔	✔	✔	
	✔			Just the value is written.

For OPC-DA property mappings, there is just one mapping operation (Get), and the corresponding table is trivial:

	Mapping Operation
Mapping Kind	**Get**
Result	Output
ErrorId	Output
Exception	Output
ErrorMessage	Output
StatusInfo	Output

Value	Output

The following table shows how (depending on the item mapping kind) the Read, Write and Subscribe operations treat their mapping arguments for OPC-UA data mappings.

	Mapping Operation		
Mapping Kind	**Read**	**Write**	**Subscribe**
Result	Output	Output	Notification Input
ErrorId	Output	Output	Notification Input
Exception	Output	Output	Notification Input
ErrorMessage	Output	Output	Notification Input
StatusInfo	Output	Output	Notification Input
AttributeData	Output	Input	Notification Input
Value	Output	Input	Notification Input
ServerTimestamp	Output	Input	Notification Input
ServerTimestampLocal	Output	Input	Notification Input
SourceTimestamp	Output	Input	Notification Input
SourceTimestampLocal	Output	Input	Notification Input
StatusCode	Output	Input	Notification Input

The Write operation in OPC-UA can either write just a value, or a value/server timestamp/source timestamp/status code quadruple. Only following combinations of inputs are therefore valid for the OPC-UA Write operation:

AttributeData	**Value**	**ServerTimestamp or ServerTimestampLocal**	**SourceTimestamp or SourceTimestampLocal**	**StatusCode**	**Outcome**
✔					Value/server timestamp/source timestamp/status code quadruple is written.
	✔	✔	✔	✔	
	✔				Just the value is written.

5.2.1.11 The Mapper Object

The mapper object is at the center of the live mapping mode. You will typically use it for two main purposes:

1. Establish the correspondences between the source OPC data, and you target .NET objects: see Mapping Your Objects.
2. Perform various operations using the mappings established earlier: Invoking the Operations.

For mapping of OPC Data Access (OPC-DA) sources, the actual mapper class is DAClientMapper. You can create an instance of DAClientMapper simply by instantiating it with one of its constructor overloads. You can also use a static DAClientMapper.SharedInstance object and avoid the need of instantiation.

For mapping of OPC Unified Architecture (OPC-UA) sources, the actual mapper class is UAClientMapper. You can create an instance of UAClientMapper simply by instantiating it with one of its constructor overloads. You can also use a static UAClientMapper.SharedInstance object and avoid the need of instantiation.

5.2.1.11.1 Mapping Your Objects

In order to create the mappings, i.e. associations between mapping sources (OPC data) and mapping targets (your object members), you typically call one of the Map method overrides on the mapper object (DAClientMapper, for OPC Data Access).

For the mapping, you can either have the mapper use a copy of its mapping context template (defined by its MappingContextTemplate property), or pass in your own Mapping Context object (see further below for details of the mapping context). In both cases, you need to specify the object to be mapped. The mapper then uses its knowledge about the object type (as given by the mapping attributes) to create and add to itself a set of mappings, one mapping for each mapped member in your object structure.

It is also possible to "undo" the mapping. To do so, you typically call one of the Unmap method overrides on the mapper object (DAClientMapper, for OPC Data Access). You can either un-map all mappings that currently exist in the mapper (if you pass no arguments), or un-map specific mappings.

5.2.1.11.2 Mapping Context

The mapping context holds information about the state of the mapping process. In OPC Data Access (OPC-DA), the mapping context is represented by an instance of DAMappingContext class. In OPC Unified Architecture (OPC-UA), the mapping context is represented by an instance of UAMappingContext class.

The state of mapping changes in the mapping context, as the mapping process proceeds from your given "starting" object, to its possible constituent objects.

For example, the mapping context contains the information about the OPC server and current OPC node, and parameters for reading and subscription. As the mapping proceeds to deeper level, the properties in the mapping context are propagated to the deeper levels as well, and they change accordingly. For example, if a member is mapped to an OPC-DA node, the NodeDescriptor property of the DAMappingContext changes to reflect the information about the node. If the member represents an OPC branch and contains another object, this new NodeDescriptor will be the basis for mapping the members of the inner object.

Refer to Propagated Parameters for descriptions of attributes that are maintained in the mapping context.

You need to make sure that enough information is provided for the mapping, either through the "starting" mapping context used with the Map method, or by means of the mapping attributes. Typically, for example, the OPC server's computer and ProgID (or endpoint URL) will not be specified through the mapping attributes, but will come from your code, so that it can be modified in run-time. In OPC-DA, you will therefore create a new DAMappingContext with properly filled ServerDescriptor, and pass it to the Map method. In OPC-UA, you will create a new UAMappingContext with properly filled EndpointDescriptor, and pass it to the Map method.

5.2.1.11.3 Invoking the Operations

Once you have your objects mapped, you can invoke operations on them. The operations available depend on the type of mapper object.

For OPC Data Access (the DAClientMapper class), following methods exist for invoking operations:

- The Get method executes the “Get”, i.e. gets the values of OPC-DA properties.
- The Read method executes the “Read”, i.e. reads the data of OPC-DA items.
- The Subscribe method executes the “Subscribe”; depending on its Boolean arguments, it either subscribes to or unsubscribes from changes of OPC-DA items.
- The Write method executes the “Write”, i.e. writes data into the OPC-DA items.

For OPC Unified Architecture (the UAClientMapper class), following methods exist for invoking operations:

- The Read method executes the “Read”, i.e. reads the data of OPC-UA node attributes.
- The Subscribe method executes the “Subscribe”; depending on its Boolean arguments, it either subscribes to or unsubscribes from changes of OPC-UA node attributes (monitored items).
- The Write method executes the “Write”, i.e. writes data into the OPC-UA node attributes.

Each operation can be invoked either on all applicable mappings currently existing in the mapper, or on a specified subset of mappings. For example, the Read method on DAClientMapper has two overloads, one with no arguments (reads all item mappings that have DAItemMappingOperations.Read included in their Operations property), and one with the IEnumerable<IDAClientMapping> argument (reads just the specified mappings).

Since you typically do not have direct access to the individual mappings created for your objects (except with Type-less Mapping), you might be asking how to get access to the subset of mappings that you need. For example, you may need to perform an OPC Read on just certain mapped object, somewhere inside the whole hierarchy.

The way to obtain the set of mapping is to query the mapper itself. The Mappings property of the mapper contains an IEnumerable<> of all mappings currently maintained by the mapper. You can filter these mappings in any way you like, testing whether they fulfill your application-defined criteria, and then perform the operation just with the filtered subset.

In order to make this task easier, some extension method exist. Following methods are available for all OPC specifications:

- AbstractMappingExtension.GetTargetObject method determines the target object of the mapping. You can use it to test whether the mapping is for “your” object.
- AbstractMappingExtension.BelongsTo method determines whether a given target object belongs to this mapping, either directly, or recursively (to any of the parent mappings).

For OPC Data Access, you can use following extension methods:

- DAClientMapperExtension.GetTarget method executes the OPC-DA "Get" operation on member of given target object, directly or recursively.
- DAClientMapperExtension.ReadTarget method executes the OPC-DA "Read" operation on member of given target object, directly or recursively.
- DAClientMapperExtension.SubscribeTarget method executes the OPC-DA "Subscribe" operation on member of given target object, directly or recursively.
- DAClientMapperExtension.WriteTarget method executes the OPC-DA "Write" operation on member of given target object, directly or recursively.

For OPC Unified Architecture, you can use the following extension methods:

- UAMapperExtension.ReadTarget method executes the OPC-UA "Read" operation on member of given target object, directly or recursively.
- UAMapperExtension.SubscribeTarget method executes the OPC-UA "Subscribe" operation on member of given target object, directly or recursively.

- UAMapperExtension.WriteTarget method executes the OPC-UA "Write" operation on member of given target object, directly or recursively.

With each of the extension methods on the DAClientMapperExtension or UAMapperExtension, you can also specify that just members with given mapping tag, or with tags fulfilling certain condition (predicate) will be affected.

The DAClientMapper and UAClientMapper objects have a Boolean QueuedExecution property (defaults to false). When set to 'true', the operations on the mapper are executed outside the calling thread, but still in the order of arrival. This allows non-blocking operation calls on the mappers.

5.2.1.11.4 Type-less Mapping

While less common, you can actually using the live mapping mechanism for establishing a direct correspondence between mapping sources and mapping targets, without having to map the types. This may be beneficial e.g. if your application just needs to pick a small number of “scattered” items to be mapped from a large OPC address space, and at the same time you won’t gain much from defining the types for objects that exist in the OPC address space.

In order to use the type-less mapping, you need to call the DefineMapping method on the mapper object, passing it the three essential pieces of information: The mapping source, the mapping itself (not yet associated with the source and target), and the mapping target. The DefineMapping method associates the mapping with its source and target, and adds the mapping to the mapper.

The example below shows how to define a new type-less mapping which maps a specified OPC-DA item to the Value member of your target MyClass object. The mapper is then instructed to invoke the OPC read operation, which will in turn store the OPC item’s value to your target object.

Type-less mapping (OPC DA) in C#

```
var mapper = new DAClientMapper();
var target = new MyClass2();

// Define a type-less mapping.

mapper.DefineMapping(
     new DAClientItemSource("OPCLabs.KitServer.2", "Simulation.Register_I4",
DADataSource.Cache),
     new DAClientItemMapping(typeof(Int32)),
     new ObjectMemberLinkingTarget(target.GetType(), target, "Value"));

// Perform a read operation.
mapper.Read();
```

Type-less mapping (OPC DA) in VB.NET

```
Public Shared Sub Main1()
    Dim mapper = New DAClientMapper()
    Dim target = New MyClass2()

    ' Define a type-less mapping.

    mapper.DefineMapping( _
```

```
            New DAClientItemSource( _
                "OPCLabs.KitServer.2",
                "Simulation.Register_I4",
                New DAReadParameters(DADataSource.Cache)),
            New DAClientItemMapping(GetType(Int32)),
            New ObjectMemberLinkingTarget(target.GetType(), target, "Value"))

    ' Perform a read operation.
    mapper.Read()

    ' Display the result.
    Console.WriteLine(target.Value)
End Sub
```

The example below shows how to define a new type-less mapping which maps a specified node in OPC Unified Architecture (OPC-UA) server to the Value member of your target MyClass2 object. The mapper is then instructed to invoke the OPC read operation, which will in turn store the OPC node's value to your target object:

Type-less mapping (OPC UA) in C#

```
UAEndpointDescriptor endpointDescriptor =
    "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
// or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
// or "https://opcua.demo-this.com:51212/UA/SampleServer/"

var mapper = new UAClientMapper();
var target = new MyClass2();

// Define a type-less mapping.

MemberInfo memberInfo = target.GetType().GetMember("Value").SingleOrDefault();
Debug.Assert(memberInfo != null);

mapper.DefineMapping(
    new UAClientDataMappingSource(
        endpointDescriptor,
        "nsu=http://test.org/UA/Data/;i=10389",
        UAAttributeId.Value,
        UAIndexRangeList.Empty,
        UAReadParameters.CacheMaximumAge),
    new UAClientDataMapping(typeof(Int32)),
    new ObjectMemberLinkingTarget(target.GetType(), target, memberInfo));

// Perform a read operation.
mapper.Read();
```

Type-less mapping (OPC UA) in VB.NET

```
Public Shared Sub Main1()

    ' Define which server we will work with.
    Dim endpointDescriptor As UAEndpointDescriptor =
            "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer"
    ' or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
    ' or "https://opcua.demo-this.com:51212/UA/SampleServer/"

    Dim mapper = New UAClientMapper()
    Dim target = New MyClass2()

    ' Define a type-less mapping.

    Dim memberInfo = target.GetType().GetMember("Value").SingleOrDefault()
    Debug.Assert(memberInfo IsNot Nothing)

    mapper.DefineMapping( _
        New UAClientDataMappingSource( _
            endpointDescriptor, _
            "nsu=http://test.org/UA/Data/;i=10389", _
            UAAttributeId.Value, _
            UAIndexRangeList.Empty, _
            UAReadParameters.CacheMaximumAge), _
        New UAClientDataMapping(GetType(Int32)), _
        New ObjectMemberLinkingTarget(target.GetType(), target, memberInfo))

    ' Perform a read operation.
    mapper.Read()

    ' Display results
    Console.WriteLine(target.Value)
End Sub
```

In order to remove the mapping added in this way, call the UndefineMapping method on the mapper object.

The example below shows how to subscribe and unsubscribe:

Subscribe and subscribe with type-less mapping in C#

```
// This example for OPC DA type-less mapping shows how to define a mapping and perform
subscribe and unsubscribe operations.

5.2.1.11.5 Error Handling in the Mapper Object

There are several types of errors that can occur in relation to live mapping, and they are treated differently. It is important to understand what happens in various situations, so that you can write code that behaves properly.

In the list below, we have tried to sort the possible types of errors by severity, starting with the most severe errors first.

A. Errors during object mapping. These are errors that are encountered when you are associating your objects

(mapping targets) with mapping sources, usually by means of calling one of the Map method overloads on the mapper object. Typically, these errors are cause by improper usage of mapping attributes, such that the mapping cannot be created at all. They are basically coding errors, and are reported by throwing a MappingException during the mapping (the Map method call).

B. Operation execution errors. These are logical errors that happen when you invoke an operation on the mapper, such as Read, Write, Get or Subscribe. Operation execution errors are similar to the errors encountered during object mapping, except that they could not have been discovered earlier. For example, you may have a conflicting combination of attributes that does not allow the OPC Write operation be performed. Operation execution errors are basically coding errors as well, and are reported by throwing an ExecutionException from the operation method invoked.

C. Update failures. The update failure means that a mapping target could not be updated with a new value. Each update failure is indicated by an UpdateFailure event raised on the mapper object. The event notification contains an Exception indicating the cause of the update failure, and a reference to the mapping source. You can hook your event handler to this event if you need some action be performed in such case.

   There may be various reasons for update failures; below are the common specific causes.

   1. Target access errors. They happen when the live mapping encounters a failure accessing your objects (mapping targets). For example, setting or getting a property on your object may throw an exception, and such exception will be caught. Target access error is represented by an instance of TargetAccessException in an update failure.
