   2. Validation errors. These are errors caused by invalid values passed to or from the mapping target. For example, you may be attempting to write a null reference DAVtq object, a null timestamp, or a null quality. Validation errors are represented by an instance of ValidationException in an update failure. Note that these are validations on the client side, not any validations made by the OPC server.

D. Mapping source problems. These are errors related to the actual mapping sources, such as OPC items or OPC properties. For example, the OPC server may be shut down, or the item ID might have changed name and is no longer accessible. Mapping source problems may actually be THE important errors for you to handle, but they have the least severity as far as the live mapping is concerned, because they are treated as just another data being mapped (and sent to your application). There are mapping kinds (see Mapping Kinds) such as Exception or ErrorId that allow you to set up members on your objects that will receive error information in case of mapping source problems.

5.2.2 OPC-UA Modelling (Preliminary)

This development model automatically provides .NET objects that logically correspond to OPC-UA information model. The operative parts of this model are internally implemented using Live Mapping.

Currently, only certain standard OPC-UA variable types are supported; custom types are not yet available. Supported concrete classes include: UAPropertyNode, UABaseDataVariable; for UA Data Access: UADataItemNode, UAAnalogItemNode, UATwoStateDiscreteNode, UAMultiStateDiscreteNode.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

5.2.2.1 How It Works

Here are the steps that you need to get started with using OPC-UA modelling approach in your code:

1. Create an instance of UAModelClient class that will use the information model resident in the OPC server. You obtain this UAModelClient object by calling a static method UAModelClient.CreateWithServerModel().
2. When you want to work with a node in the OPC server, obtain the corresponding node object by calling the GetNode method on the UAModelClient object. There are also extension methods that are useful to obtain nodes with a type that you expect. For example, to obtain a node for an analog variable of type TValue, use the GetAnalogItemNode<TValue> extension method.
3. a. If you want to read data from the node, call the ReadNode method on the UAModelClient object, passing it the node object, and optionally the so-called modelling tag. Use UAModellingTags.VariableValue to operate only on the value of the variable. Use UAModellingTags.VariableProperty to operate on all variable properties. After the ReadNode call, the properties on the node object contain the values obtained. For example, the Value property contains the current value of the variable. Or, the EURange property contains the engineering units range.
   b. If you want to write data into the node, set the properties of the node objects (such as the Value property), and then call the WriteNode method on the UAModelClient object. You can optionally use the modelling tags, as with the ReadNode method.
   c. If you want to subscribe to (or unsubscribe from) changes in the node data, call the SubscribeNode method on the UAModelClient object, passing it the "active" flag (determines whether you want to subscribe or unsubscribe) and the node object. You can optionally use the modelling tags, as with the ReadNode method. The properties of the node object (such as the Value property) will be automatically be updated with changes from the OPC server.

5.2.2.2 OPC UA Node Types

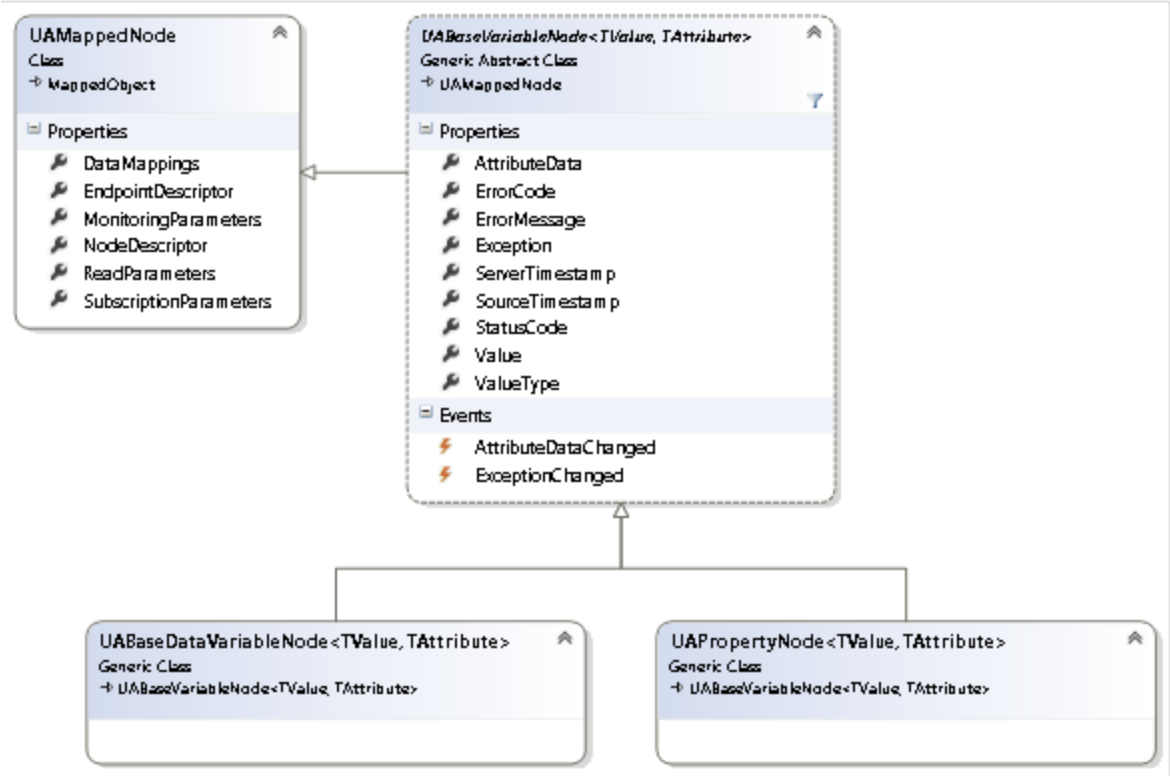
OPC Data Client contains definitions of certain OPC-UA node types that can be used with the modelling. Currently, these are the only node types supported, and the list cannot be extended. Future OPC Data Client versions will support the creation of use of custom node types with OPC-UA modelling.

The .NET classes for various OPC-UA node types use an inheritance scheme that follows the inheritance hierarchy in OPC-UA information model. The UABaseVariable is the root of this hierarchy; in itself, it derives from UAMappedNode, which means that it contains meta-information about itself, such as the EndpointDescriptor or NodeDescriptor, and also parameters that define details of operations that performed on the node – such as ReadParameters, or SubscriptionParameters and MonitoringParameters.

Each UABaseVariable contains properties that describe the state of the node either individually (Value, StatusCode, timestamps, ...), or in a summary way (AttributeData). There are also properties that give information about errors encountered during the operations (Exception, ErrorId, ErrorMessage).

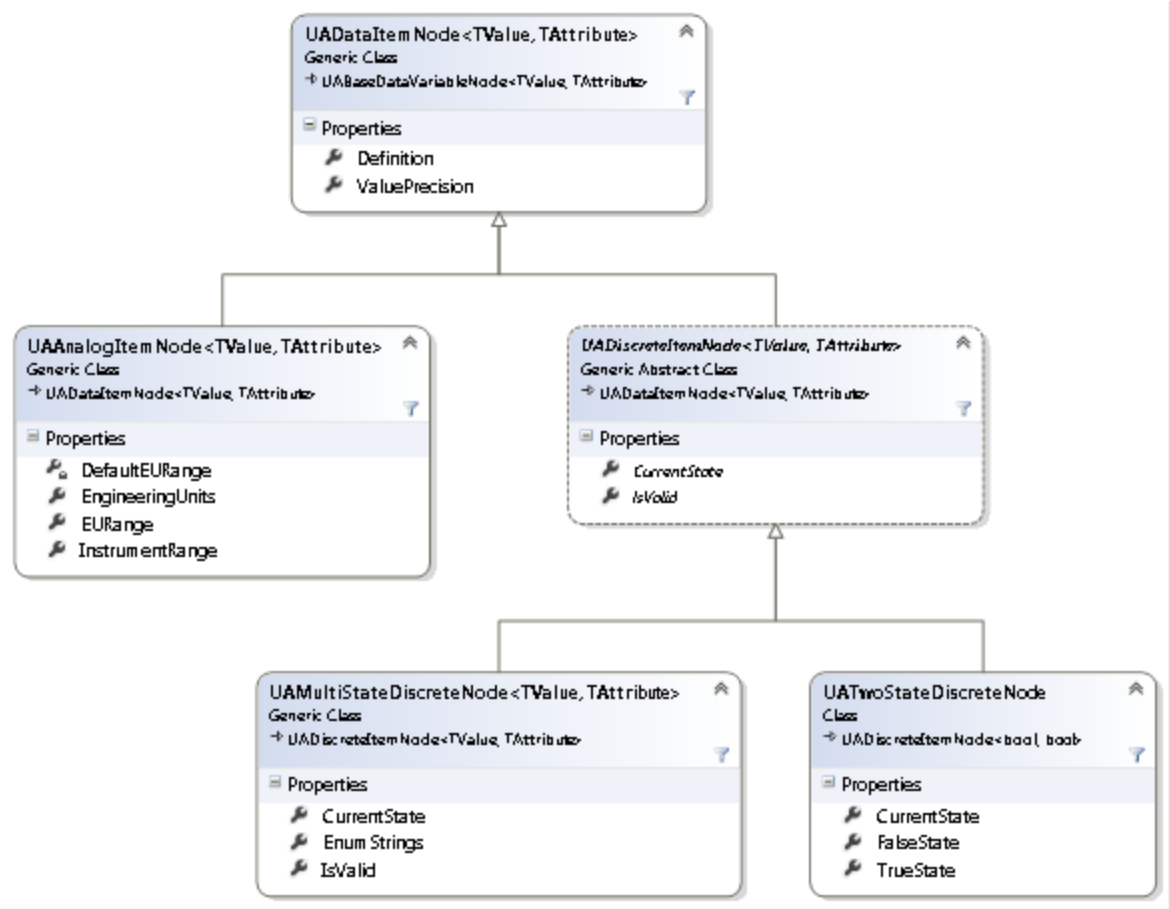
You can hook to AttributeDataChanged and ExceptionChanged events to get your code invoked whenever the relevant data of the OPC-UA variable changes.

The hierarchy of basic OPC-UA node type classes, and their most important members, are shown on the following diagram.



For use in Data Access, OPC-UA defines additional variable types, and they are reflected in OPC Data Client .NET node types as well. When working with OPC-UA Data Access modelling, you will most likely use at least one of the following classes: UAAnalogItemNode (for analog variables), UATwoStateDiscreteNode (for digital – Boolean variables), or UAMultiStateDiscreteNode (for enumeration-type variables).

The hierarchy of OPC-UA Data Access node type classes, and their most important members, are shown on the following diagram.



The classes contain members that correspond to OPC-UA properties defined for these kind of variables. For example, the Definition, ValuePrecision, EngineeringUnits, EURange etc. properties all contain information that further describes the variable. In addition, for discrete variables, the classes provide transformation between the "raw" values of the variable, and their string representation. The CurrentState property contains the current value of the variable, expressed as a string.

5.3 Live Binding Model

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

> This functionality is not yet available for OPC UA PubSub.

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

In This Topic

Microsoft .net With live binding development model, no manual coding is necessary to obtain OPC connectivity. You simply use the Visual Studio Designer to configure bindings between properties of visual or non-visual components, and OPC data. All functionality for OPC reads, writes, subscriptions etc. is provided by the OPC Data Client components.

Note: Several binding technologies for.NET already exist, some directly from Microsoft. These technologies are mainly focused on binding database or similar data, and they are not well suitable for automation purposes like OPC. We therefore had to implement a new binding model. We use the term “live binding” so that it is clearly distinguished from other binding technologies used; it also reflects the fact that this kind of binding is well-suited for real-time, “live” data.

The Live Binding model is currently available for:

- Windows Forms (or UI-less) containers, and
- Windows Presentation Foundation (WPF).

You can use it with OPC Data Access, OPC XML-DA, or with OPC Unified Architecture data.

An important aspect of the live binding model is that it is not limited to or associated with any particular set of UI controls. It works by extending the features of existing controls, and providing functionality on top of what the controls already do. Live binding works well with standard Microsoft controls, but also work with controls from other vendors. This approach gives the live binding an enormous power, because you can combine the advanced features of free or commercial controls with the OPC connectivity.

In the examples installed with the product, we provide a demonstration of the integration capability described above.

There are demos that show how Live Binding can be used with several 3rd party products, some aimed directly at industrial automation area.

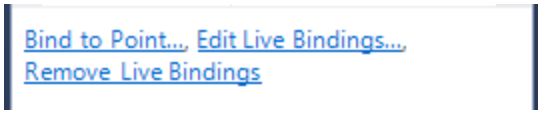
Live Binding Features

Live Binding works with OPC Data Access ("Classic") and OPC Unified Architecture servers (for data access). Its features include:

- You can bind to any OPC item, node attribute or property.
- You can bind .NET object properties, methods, and even sub-members. Members of extender components (such as ToolTip or ErrorProvider) can be bound, too!
- Works with subscriptions, but also one-time reads and writes.
- Bindings can be grouped for easier configuration and control.
- You can convert and format the values in various ways.
- Design just by dragging components from Toolbox and configuring them.
- Work with array elements using the element extraction feature, and built-in read-modify-write algorithm.
- Different binding kinds such as Value, Quality, Timestamps, ErrorMessage, and many more.

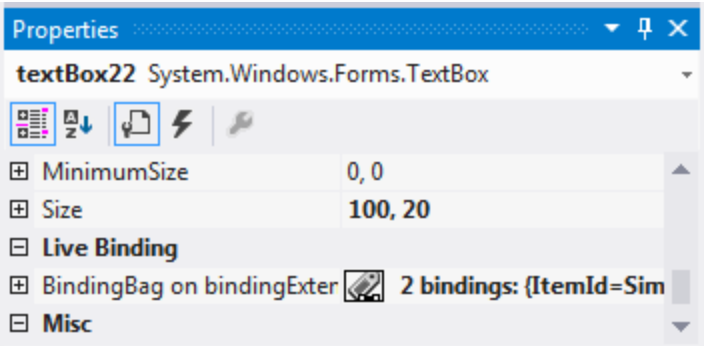
Live Binding Fundamentals

The live binding model is allowed by the BindingExtender, PointBinder and DAConnectivity (or UAConnectivity, CompositeConnectivity) components that you place from the toolbox items onto the component tray. You can then use extender commands in the Properties window, or on the context menu of each component (control), to bind the component’s properties to OPC data:

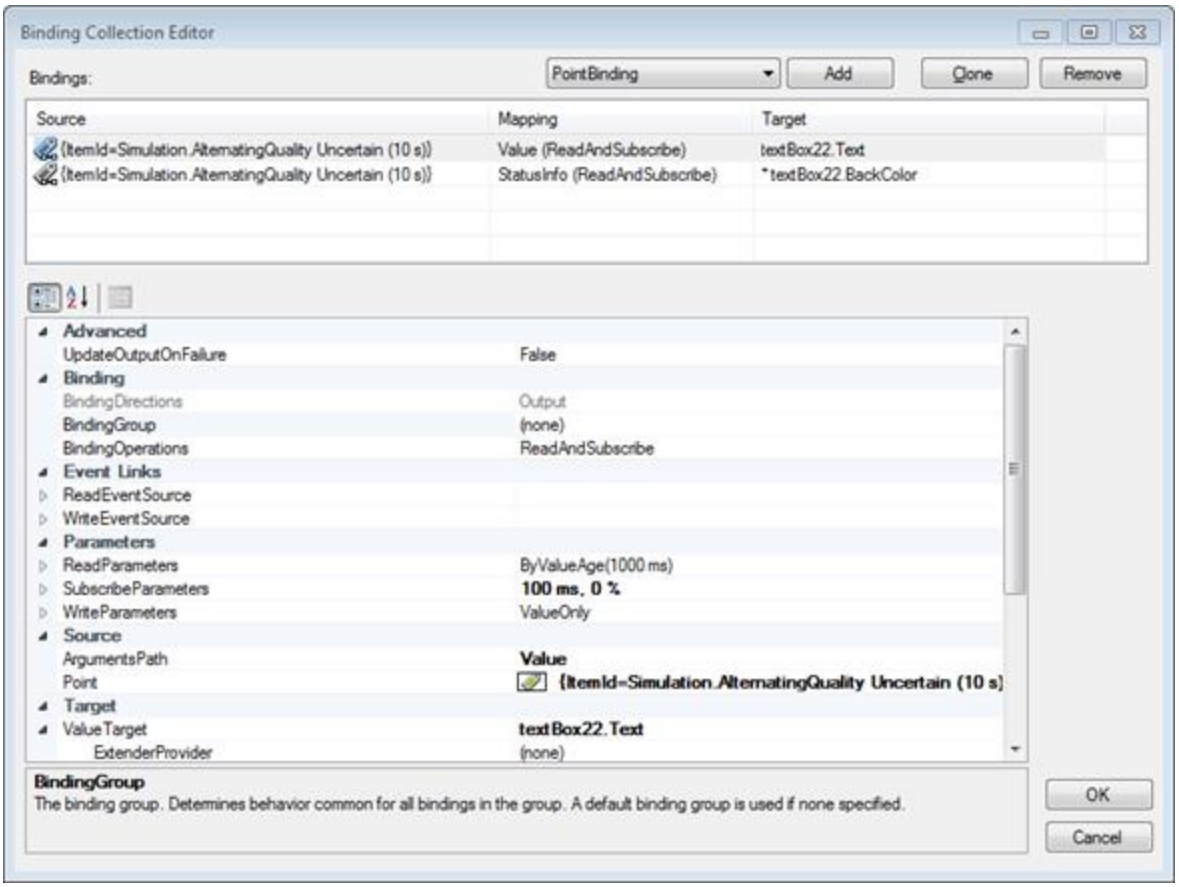


After selecting the “Bind to Point” command, you select the OPC data you want to bind to, and you are done. The

currently configured bindings appear as additional entries in the Properties window:



You can also invoke a full-featured binding editor, and configure all aspects on bindings – either on individual component (control), or for a whole container (form) at once:



5.3.1 Live Binding Model for OPC Data (Classic and UA)

Live Binding is supported to OPC data points, i.e. identified values (items, nodes) that are changing over time. Live Binding is currently not available for other types of OPC data, such as OPC alarms, events or conditions.

Do not confuse the live binding model with live mapping, also provided by OPC Data Client. The main differences between the two are that

- live binding is for UI (User Interface), and is therefore visual, both in design and in runtime, and
- live binding works with individual object members, and not on whole types.

Following resources will help you get started with Live Binding:

- The Getting Started section in this document: Contains instructions on how to create an application with live binding in a few steps.
- For OPC-DA in Windows Forms, the "Live Binding Demo" application that is installed with the product; its source code is contained in the **WindowsForms\LiveBindingDemo** project. The application contains annotated live binding configurations for typical scenarios.
- For OPC-UA in Windows Forms, the "UA Live Binding Demo" application that is installed with the product; its source code is contained in the **WindowsForms\UALiveBindingDemo** project. The application contains annotated live binding configurations for typical scenarios.
- For OPC-UA in WPF, the "WPF Live Binding Demo" application that is installed with the product; its source code is contained in the **WPF\WpfLiveBindingDemo** project. The application contains annotated live binding configurations for typical scenarios.

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

5.3.1.1 Live Binding Overview

The live binding allows you to extend your controls and components with one or more *bindings*. The binding can perform various *operations*, such as read or write values, or continuously update (subscribe). The data reside in the *binding source* – e.g. in OPC Data Access or OPC Unified Architecture server, and are provided through a *connectivity* component for that binding source. The other end of the binding is the *binding target*. The usual binding targets can accept or provide values of various types, and are therefore referred to *as value targets*. When values are transferred between to or from the target, *value conversions* can be made – using *string formats*, or *converters*.

The live binding functionality is provided by a generic *binding extender*. The specific types of bindings are made available by *binding providers*, which are encapsulated in *binder* components. The binding extender keeps *binding bags*, i.e. collections of bindings for each control being extended.

Operations on bindings can be tied to *event sources* and thus performed automatically with events in your application. In order to handle multiple bindings together, it is possible to define *binding groups* and assign bindings to them. *Binding templates* can be defined to make it easier to create new bindings that share similar characteristics.

The objects and terms briefly mentioned above are described in more detail sin the subsequent chapters.

5.3.1.1.1 Value Targets

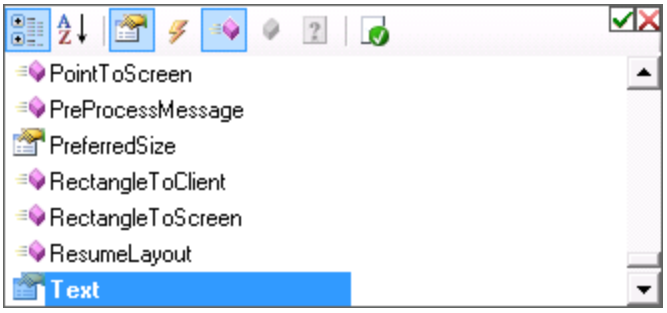
The *value target* represents a place in your application where values can be sent to or obtained from. You configure the value target by selecting the TargetComponent and TargetMember. A typical value target is a property of a visual control on your form. For example, in order to send values to the Text property of the TextBox control, you would set the TargetComponent to the text box control itself, and the TargetMember to a string "Text".

It is also possible to target the so-called extender properties. In such case, you also need to select the ExtenderProvider component that actually provides the extender property. Typical and useful extender providers are the ToolTip and ErrorProvider components for Windows Forms.

When you select the TargetComponent (and the TargetMember is not set yet), the live binding system attempts to determine the TargetMember that you want to use. For example, the most commonly used property of the TextBox control is the Text property, so it makes sense to provide that as a default. This default member name is determined using several hints, including the DefaultBindingProperty and DefaultProperty attributes on the target component, and other characteristics.

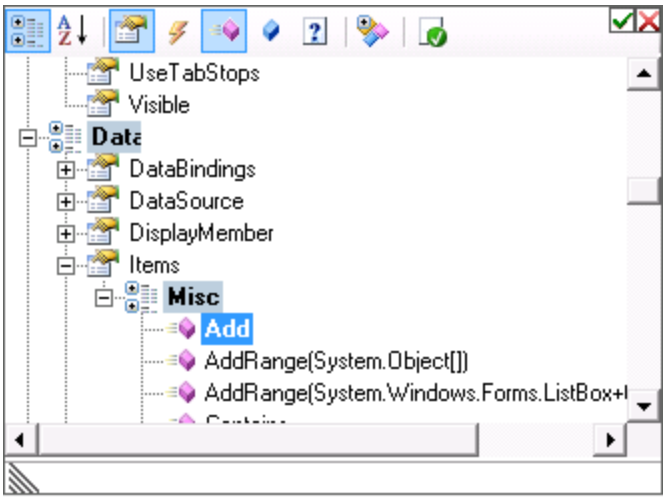
Not all controls (especially 3rd party controls) have their default members marked up (or, they may be marked up inappropriately for live binding). The live binding contains some built-in knowledge that allows proper selection of the default target member for popular controls, even in such cases. If you still get an improper target member selected for you by default, you can always change it to any control's member you like.

You can type in the name of the target member, or you can select it using the drop-down editor (picture below).



The member name editor shows different icons for different member kinds, annotates the members with number of overloads if needed, shows member information (such as type, and description) in the tooltip, allows filtering (e.g. Properties, Event, Methods, Fields), alphabetical or categorized view, and reverting to default member.

When binding .NET members, you can specify not just a member name, but a whole path to it – i.e. it is possible to bind sub-members as well. The path is a sequence of member names, separated by dots. For example, for binding on a ListBox component, it is possible to set the target path to "Items.Add", which means that we bind the Add method of the Items collection of the ListBox (in effect, this will append incoming values as new values to the ListBox). If you want to specify the path (sub-members) and not just a single member, you use the TargetPath property instead of just TargetMember. By pressing a down-arrow symbol next to the path, you are offered a tree of available members and sub-members, with various filtering and sorting capabilities:



When binding .NET members (methods) that have multiple overloads, it is possible to specify the desired method signature using a type name in parenthesis, added to the element path. For example, if you wanted to bind the Add method of the Items collection of a ListView, there are two overloads that take one input argument, and the Live Binding would not know which one to use. By using a target path "Items.Add(System.String)", you will instruct the Live Binding to use the overload that accepts string as an input.

5.3.1.1.2 Binding Operations

There are several things you can do with OPC Data: you can read from them, write to them, or subscribe to their changes. Not all bindings should be involved in all operations, and you therefore need to specify the operations that are of interest to you.

You can choose one of the following values, or their combination:

- PointBindingOperations.Read: A Read operation.
- PointBindingOperations.Write: A Write operation.
- PointBindingOperations.Subscribe: A Subscribe operation.

If you want a combination, you can use a predefined symbolic name such as ReadAndWrite, ReadAndSubscribe, etc. By default, the BindingOperations argument is set to PointBindingOperations.ReadAndSubscribe, meaning that the binding will be involved in Reads and Subscribes, but not in Writes.

5.3.1.1.3 Bindings

A binding is a correspondence between two entities that allows information be passed between them (either in one of the directions, or in both directions).

The main parts of binding are:

- **(Binding) Source**: The external data you want to bind to. Here you select e.g. the OPC item, update rate etc. You can also select which "part" of the data you want to bind to (e.g. just the value, or just the quality information, etc.).
- **(Binding) Target**: Defines element in your application that will be bound to the binding source. This is typically a value target (see Value Targets).
- **Binding Operations**: Which operations the binding is involved in.
- **Binding Groups**: Which binding group the binding belongs to.
- **Value Conversion**: Allows you to convert the values on their way to/from the binding target.
- **Event Links**: Defines events in your application that will automatically cause binding operation be performed.

The types of bindings that are available depend on the binder in use (see further below). For the (most common) PointBinder, there is just one type of binding available, a PointBinding. The point binding can be e.g. for an OPC-DA item, an OPC-DA property, or for OPC-UA data (node attribute).

There may be multiple bindings associated with a control. With this feature, you can, for example, bind a value (converted to string) to the actual text box's text, while binding the status information to its color.

5.3.1.1.4 Binding Bags

A binding bag is essentially a collection of bindings, with a reference to a common component to which the bindings belong. The live binding system keeps a binding for each component that is extended with bindings, and also allows you to access a common binding bag that represents all bindings defined in a container.

One binding bag can hold bindings of different types, and bindings that have different sources.

5.3.1.1.5 Binding Extender

The binding extender is a central piece of live binding model. It is represented by the BindingExtender component; this component must be present on the component tray (of your form or window) in order to enable it for live binding.

The main purpose of the binding extender is to keep track of bindings defined on each control in the container (form), and provide extender properties to them.

The binding extender is generic; it does not have a specific knowledge about types of bindings that can be used. The available binding types are defined on the binding extender by a binder (or binders) that register with it. For explanation of binders, see further below.

5.3.1.1.6 Binders and Binding Providers

While the binding extender is a generic coordination component without specific knowledge about possible types of bindings, the *binding provider* is a component that is specific to certain technology and defines binding types tailored to that technology.

A binding provider has the ability to create one or more types of bindings, as necessary for the technology it covers. Binding providers exist in form of *binder* components; the binder is a binding provider (can create new bindings) with certain additional capabilities, such as event linking, and ability to perform operations on bindings.

Each binding provider needs to register itself with the binding extender; this is done by properly setting the BindingExtender property of the binder. When you place the binder component from the Toolbox Items to your form's or window's component tray, this setting is already made for you.

The most commonly used binder component is the PointBinder, which is described further below in a separate chapter. The PointBinder provides a unified approach to live binding; it merges the commonalities between OPC "Classic" and OPC Unified Architecture bindings into a single component.

Note: Earlier, OPC Data Client had used separate DABinder (for OPC Data Access) UABinder (for OPC Unified Architecture) component. They are now obsolete.

5.3.1.1.7 Event Sources

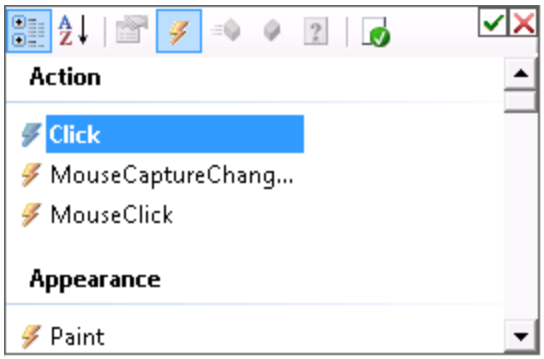
The *event source* represents a place in your application where events are generated. You configure the event source by selecting the SourceComponent and SourceMember. A typical event source is a Click event of a Button on your form.

Event sources are used in live binding to automate actions that would otherwise have to be implemented in the code by writing an event handler.

For example, if you are designing a form or window with HMI functionality, you probably want it to subscribe to value changes of the configured items when it is shown. This can be achieved by properly setting the OnlineEventSource event source of the BindingExtender component (and indeed, when you place the BindingExtender from the toolbox items onto a component tray, this event source is pre-set like this already).

Similarly, you may want to write some value into a bound OPC item when a button is clicked. Instead of writing an event handler, you can simply configure the WriteEventSource on the binding (or binding group) to the Click event of the Button, and you are done.

You can type in the name of the source event, or you can select it using the drop-down editor (picture below).



The member name editor shows member information (such as type, and description) in the tooltip, and allows alphabetical or categorized view, and reverting to default member.

You can specify not just a member name, but a whole path to it – i.e. it is possible to bind sub-members as well. The path is a sequence of member names, separated by dots. If you want to specify the path (sub-members) and not just a single member, you use the SourcePath property instead of just SourceMember. By pressing a down-arrow symbol next to the path, you are offered a tree of available members and sub-members, with various filtering and sorting capabilities.

5.3.1.1.8 Binding Groups

A *binding group* has the ability to handle multiple bindings together. For example, you can create a binding group, assign several bindings to it, and then have them all read or written by a single command.

The use of binding groups is optional. If you do not assign a binding to any binding group, it will belong to a *default binding group*, which always exists on the binder component.

5.3.1.2 Point Binder

The point binder (represented by a PointBinder component) provides live binding to generic data points (see further below). It supports just one type of binding – a PointBinding; however, the point binding type is so generic that it can easily describe OPC-DA "Classic" items, properties, OPC-UA nodes (attributes), or just about any other point-based data source.

The point binder makes use of the **Connectivity Model (Section 6.2)**, descrined in a separate section. Please refer to the relevant parts of documentation for information about the Connectivity Model.

In This Topic

Connectivities

Connectivities (Section 6.2.1) provide access to data sources.

The developer will usually start the live binding by placing one of these connectivity components from the Visual Studio **Toolbox** onto the component tray (in Windows Forms, by dragging from the **Toolbox** to the design surface of the form; in WPF, using the Component Tray context menu command, and the **Component Tray Editor** dialog then).

Notice that after placing any of the connectivity components onto an empty component tray, three components will appear below on the component tray: Besides the one for the connectivity itself, there will be one for the PointBinder, and one for BindingExtender.

If, after placing a connectivity component to a component tray, the PointBinder and the BindingExtender **components are not placed onto the component tray automatically, make sure that the target framework of the project is set to ".NET Framework 4.7" or later.**

Points

Points (Section 6.2.2) identify the pieces of data the Live Bindingg works with.

Point Editor

Point Editor (Section 6.2.3) is the dialog used to select, view or modify points.

Parameters

Parameters (Section 6.2.4) determine how the data will be accessed.

Arguments and Results

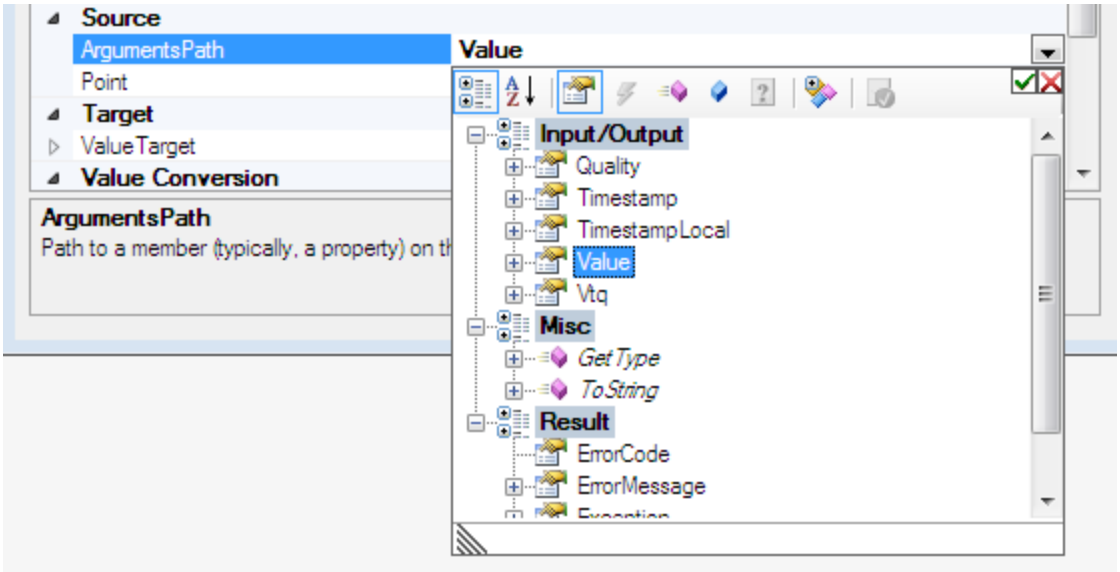
The **Arguments and Results (Section 6.2.5)** are the actual data the binding operation transfers, i.e. the "what".

The PointBinding has an UpdateOutputOnFailure property (defaults to 'false'). Normally, when an operation (such as OPC read) fails, and you are binding to an operation output, nothing happens - the binding output is not updated. For example, a text bound to an OPC data value continues to display the last known value. When the UpdateOutputOnFailure property is set to 'true', the binding output will always be updated. In our example, the text box will be cleared in case of operation failure.

5.3.1.2.1 Arguments Path

When making a binding, you are basically connecting a value target (typically, a property on a visual control) with an argument (described in the above chapter). The argument being used is specified using an *argument path*. An argument path can be simply a property name (name of the argument), such as Value, or a sequence of member names (separated by dots) that determines the path into the argument; for example, Quality.StatusBitField.

In the Visual Studio designer, the arguments path can either be typed in, or you can select using a drop-down editor, as on the following picture:



A binding can be involved in multiple binding operations (e.g. read and write), but there is just a single arguments path selection for the whole binding, and the set of arguments might be different for each operation. The arguments path should be valid for all the binding operations that are enabled on the binding. The drop-down editor offers a combined view of the possible arguments. For this reason, argument categories can change (by combining) as well: For example, in OPC DataAccess, a Value is an output in the Read operation, but it is an input in the Write operation. It is therefore shown under the Input/Output category, when both Read and Write binding operations are enabled on the binding.

5.3.1.2.2 Parameter Templates

When you create new bindings, often they share many common characteristics. For example, you may be binding to OPC items all residing in the same OPC server, or using the same parameters, such as the update rate.

In order to make it easier to create such similar bindings, parameters of newly created bindings are taken from *parameter templates*.

For OPC Data Access (OPC-DA), you can configure following templates on the DAConnectivity component:

- ItemReadParametersTemplate: OPC-DA read parameters, such as the data source (cache, device, and so on), in newly added bindings to OPC items.
- ItemSubscribeParametersTemplate: OPC-DA group parameters in newly added bindings to OPC-DA items.
- ItemWriteParametersTemplate: OPC-DA write parameters (such as whether just the value, or the whole VTQ triple should be written) in newly added bindings to OPC-DA items.

For OPC Unified Architecture (OPC-UA), you can configure following templates on the UAConnectivity component:·

- AttributeReadParametersTemplate: OPC-UA read parameters (such as the maximum value age) in newly added bindings to OPC-UA attributes.
- AttributeSubscribeParametersTemplate: OPC-UA subscription and monitoring parameters (such as the sampling interval, or data change filter) in newly added bindings to OPC-UA attributes.
- AttributeWriteParametersTemplate: OPC-UA write parameters (such as whether just the value should be written) in newly added bindings to OPC-UA attributes.

Templates have meaning only in the designer; they are not used in runtime.

5.3.1.2.3 Queued Execution

With the help of QueuedExecution property on the PointBinder, the developer can choose that the operations (such as Write-s) are performed outside the calling thread, and therefore do not block. Typical usage involves a one-time Read or Write linked to a click on a button, which would otherwise block the user interface until completed.

The Boolean QueuedExecution property defaults to 'false'. When set to 'true', the operations on the binder are executed outside the calling thread, but still in the order of arrival. This allows non-blocking operation calls on the binder.

5.3.1.3 Value Conversions, String Formats and Converters

When values are transferred to or from the target, *value conversions* can be made – using *intrinsic conversions*, *string formats*, or *data converters*.

In This Topic

Intrinsic Conversions

The intrinsic conversions do not have to be configured, and are applied automatically when needed.

The Live Binding infrastructure contains following intrinsic conversions :

- System.Drawing.Color is converted to System.Windows.Media.Color when the target is of that type. This allows to use colors in the same way in both Windows Forms and WPF.
- System.Drawing.Color is converted to System.Windows.Media.SolidColorBrush when the target is of that type. This allows to use colors in the same way in both Windows Forms and WPF.

String Formats

In order to format the bound value according to a string format, simply set the StringFormat property of the binding. An empty string means no formatting. The format string is constructed according to usual .NET rules, and can contain following placeholders:

- {0}: The value.
- {1}: The type of the value (or null if the value itself is null)

The string formatting is only applied in one direction – for values being transferred from the binding source to the binding target.

In addition to formats defined by the .NET Framework, OPC Data Client defines format strings for various its types, and especially the types used in Live Binding, such as DAQuality, DAVtq, UAAttributeData, UAStatusCode, etc. This makes it easy to format compound values for display purposes, without having to write any code. For details, please refer to Format Strings in the Reference.

Data Converters

When string formatting is not sufficient, any kind of conversion can be made using data converters, and possibly in both directions. Data converters are objects that implement the IDataConverter interface. You can place converters on the design surface of the form, and then select from them for the Converter property of any binding.

OPC Data Client ships with several data converters, described in the subsequent chapters.

Besides using the data converter(s) that ship with the product, you can create your own data converter objects or components, and assign them to your bindings.

5.3.1.3.1 The LinearConverter Component

The LinearConverter component provides a linear conversion and its inverse, and also (optionally) allows output value clamping. The linear conversion is useful for proper scaling of values when the underlying OPC source does not directly have the desired value.

You configure the parameters of the linear conversion so that the X1 value converts to Y1, and the X2 value converts to Y2. Other values are interpolated or extrapolated according to these settings.

For values that fall outside the given limits, you can choose one of the following behaviors:

- Normal. The off-limit condition is ignored, the value is converted as usual (i.e. extrapolated, in this case).
- Error. An exception is thrown.
- Clamp. The output value is clamped at the limit.

5.3.1.3.2 The StatusToColorConverter Component

This type of data converter is useful if you want to change some of the control's colors (e.g. background or foreground) according to the status of the bound source. For example, you may want the background of the text box turn to red color if there is an error related to the source.

The StatusToColorConverter can convert several types of values on its input. On its output, it provides a Color value that it chooses from one of the four colors that you can configure: UnknownColor, NormalColor, WarningColor and ErrorColor. Each color corresponds to one state, and the possible state choices are given by the StatusInfo enumeration: Unknown, Normal, Warning, and Error.

The possible input values to the StatusToColorConverter are converted as follows:

- A null reference converts to NormalColor.
- A StatusInfo.Normal converts to NormalColor, a StatusInfo.Warning converts to WarningColor, a StatusInfo.Error converts to ErrorColor, and a StatusInfo.Unknown converts to UnknownColor.
- An Exception-typed value converts to ErrorColor.
- Empty String-s convert to NormalColor, non-empty String-s convert to ErrorColor.
- Zero integers convert to NormalColor, positive integers convert to WarningColor, negative integers convert to ErrorColor.
- A true Boolean converts to NormalColor, a false Boolean converts to ErrorColor.

Several types in OPC Data Client provide built-in conversion to StatusInfo enumeration, and can therefore be used as inputs to StatusColorConverter as well.

Following types support conversion to StatusInfo in OPC Data Access:

- DAQuality
- DAVtqResult
- EasyDAItemChangedEventArgs

Following types support conversion to StatusInfo in OPC Unified Architecture:

- EasyUADataChangeNotificationEventArgs
- UAAttributeDataResult
- UAStatusCode

The rules and built-in conversion are design in such way that you can easily use various kinds of bindings with the StatusToColorConverter component. For example, if you set the ArgumentsPath property of the binding to Exception, it will convert to one of two colors. Even better, if you set the ArgumentsPath of the binding to StatusInfo, it will properly convert to one of all four possible colors.

5.3.1.4 Live Binding in the Designer

The beauty of the live binding is that it can be set up without any manual coding. This means that there has to be a tight integration with the development environment (IDE), i.e. Visual Studio.

This chapter describes the various places where the live binding in integrated with the Visual Studio and its designer features.

> ⚠ While the main principles of the Live Binding remain the same regardless of the application, some of its aspects differ in design time. The differences between designing in Windows Forms and WPF are described in the subsequent chapters, where applicable.

5.3.1.4.1 Preparing for Live Binding

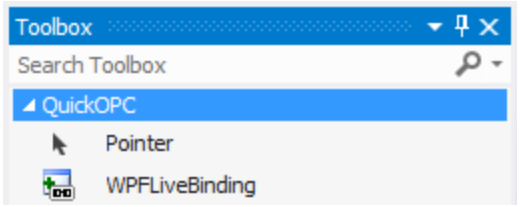
Windows Forms

No special preparation is needed in Windows Forms projects before you can use Live Binding. Specifically, the Component Tray and Toolbox Items (described in subsequent chapters) are automatically available to you in Visual Studio in Windows Forms projects.

In This Topic

WPF

In WPF, each window that you want to use with Live Binding needs to be prepared for it first, by initialize the support for Component Tray in it. To do so, drag the WPFLiveBinding component icon from the Visual Studio **Toolbox** to the design area of your WPF window.



A **Component Tray Editor** dialog appears. You can add components to it right now, or later; just make sure that you end the dialog by pressing the OK button this first time, in order for the Live Binding support be properly initialized in the designed window.

Note: If you do not see the WPFLiveBinding item in the Toolbox, or if nothing happens after dragging it to the design area, verify that your project is set to target the .NET Framework 4.7 or later.

5.3.1.4.2 Component Tray

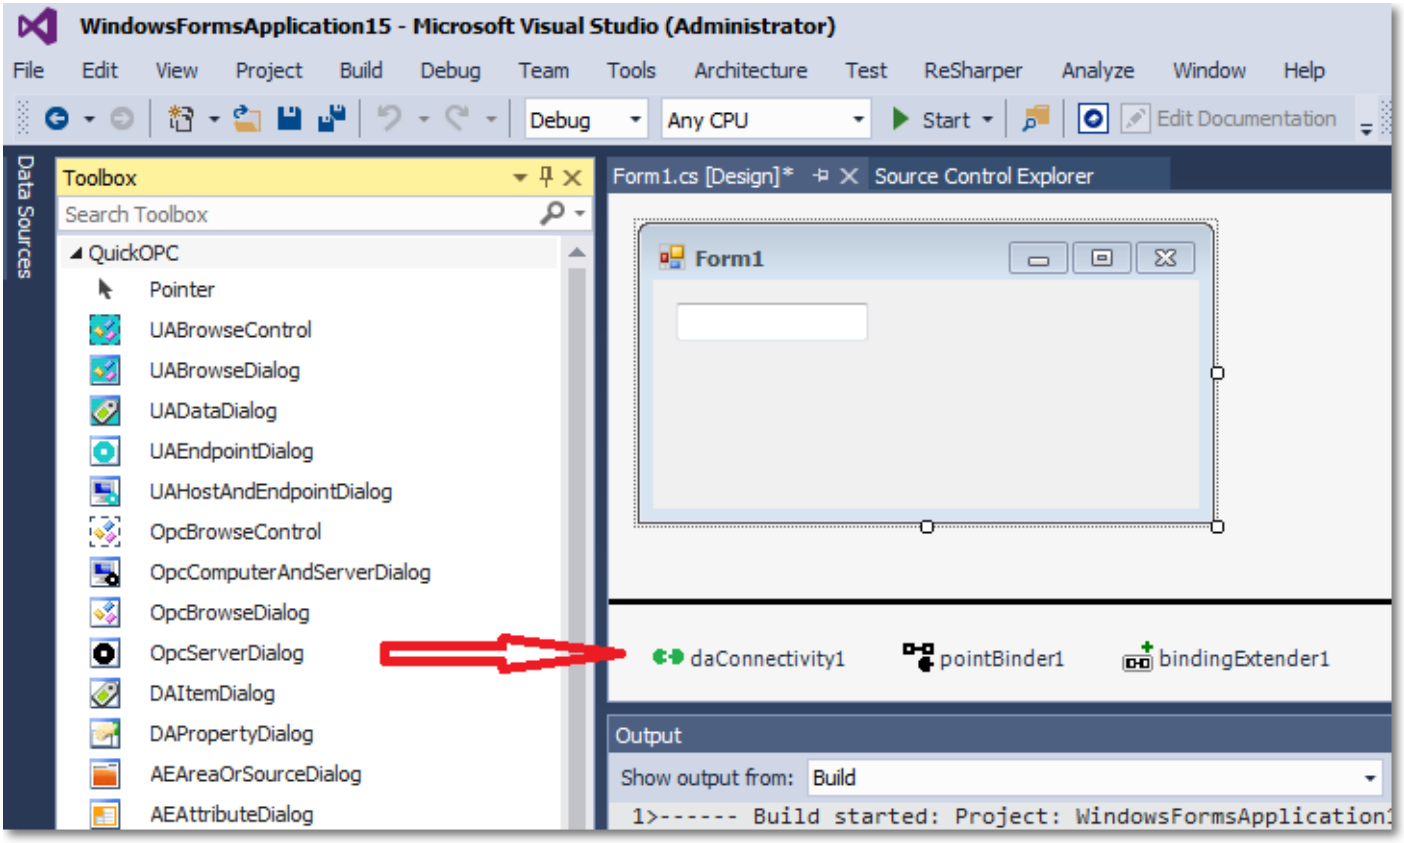
The Component Tray shows icons for nonvisual items in the designer. It allows you to work with nonvisual items separately from the controls on the form or the window being designed.

Wherever this documentation refers to a Component Tray, it needs to be interpreted depending on whether you are working with a Windows Forms or a WPF project, as described below.

In This Topic

Windows Forms

In Windows Forms, the Component Tray is provided by Visual Studio itself. It appears at the bottom of the Windows Forms Designer, as shown on the following picture:



Following operations are available:

- To add an item to the component tray, drag it from the Visual Studio **Toolbox** to the component tray area.
- To remove an item from the component tray, select it, and press the ***Delete*** key. Alternatively, after selecting the item, invoke the Delete command from its context menu, or Edit -> Delete from the main menu.
- To view or modify properties of an item on the component tray, select the item first, and then use the **Properties** window of the Visual Studio.

Changes you make to the Component Tray are reflected in the code file that the Visual Studio designer generates and

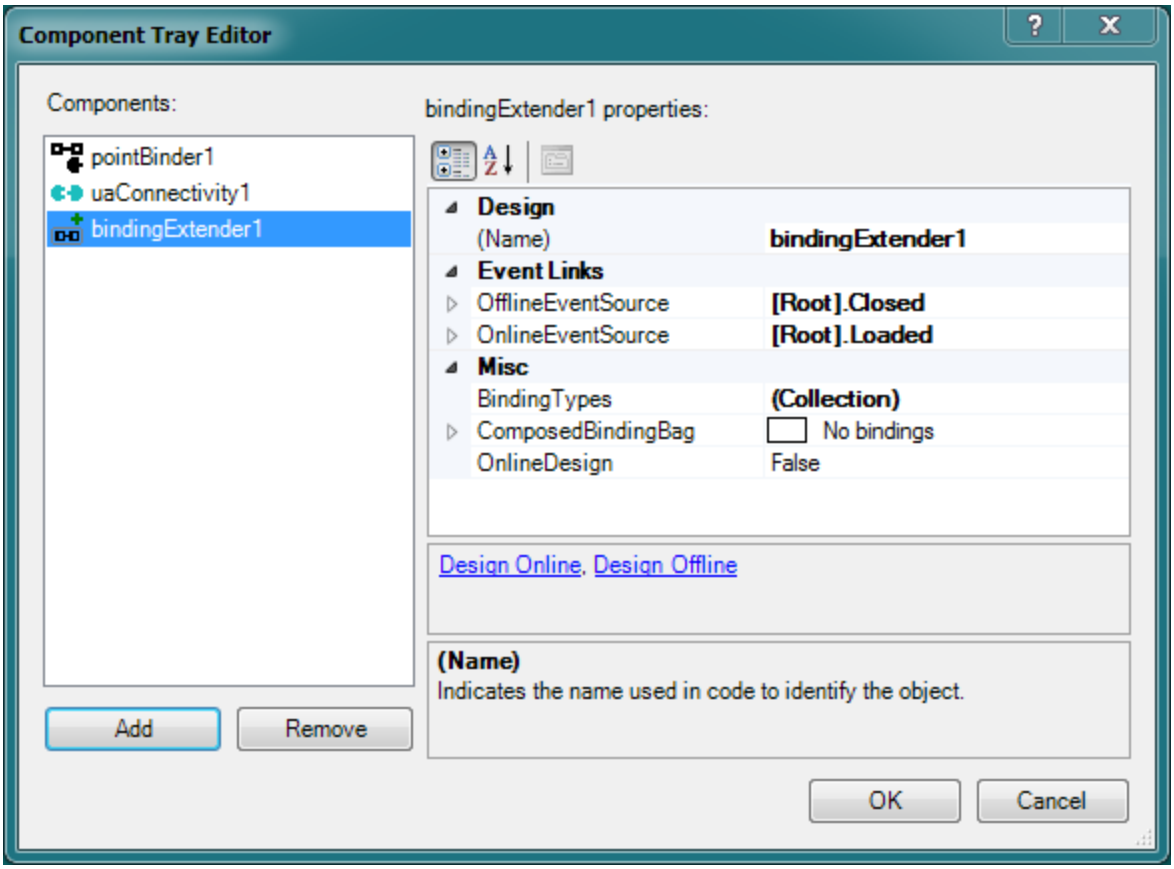
maintains for your form.

It is, of course, also possible to modify the generated code by hand, but we recommend against doing so unless you have a compelling reason for that, and know very well what you are doing.

WPF

Traditionally, WPF uses XAML to describe visual components only. For this reason, the WPF Designer does not show a component tray. In Live Binding for WPF, its functionality is provided by an add-on dialog, a **Component Tray Editor**.

In order to invoke this dialog to view or modify the items in the component tray, right-click in the design area of your WPF designer, and select the Component Tray context menu command.



Following operations are available:

- To add an item to the component tray, press the Add buton, and in the **Toolbox Items** dialog (see subsequent chapter), select the item and press OK.
- To remove an item from the component tray, select it in the **Components** list, and press the Remove button.
- To view or modify properties of an item on the component tray, select the item in the **Components** list first, and then use the property grid on the right hand side of the dialog.

Changes that you make to the Component Tray are reflected in the XAML code that the Visual Studio Designer generates and maintains for your window. Specifically, they are placed into the following XAML element:

```
<ComponentModel:Live.ComponentBag>
```

In the XAML tab of the WPF designer, it is also possible to view and modify properties of component tray items in the **Properties** window of the Visual Studio.

It is, of course, also possible to modify the generated markup by hand, but we recommend against doing so unless you have a compelling reason for that, and know very well what you are doing.

5.3.1.4.3 Toolbox Items

> ⚠ Caution: Potentially confusing terminology here. Read carefully please. "Toolbox Items" do not always reside in "Toolbox" !

In This Topic

In Visual Studio, the main place where various components originate their way to your project is the Visual Studio **Toolbox**.

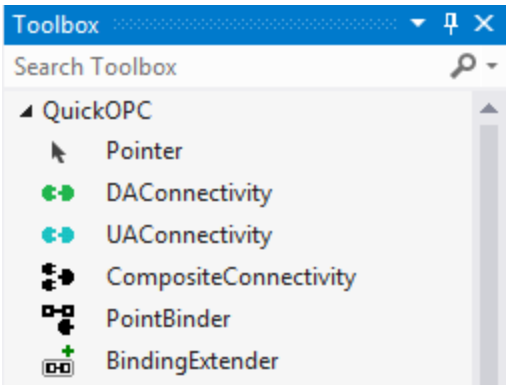
- In Windows Forms (and Web Forms), the **Toolbox** shows both visual, and nonvisual components. Toolbox Items are shown directly in Visual Studio **Toolbox**.
- In WPF, however, the **Toolbox** can only show visual components (controls). In The Live Binding uses nonvisual components as well, so in order to support them, we have added a dialog from which the components can be chosen added to Component Tray. This dialog, used for selection of nonvisual components, is referred to as the **Toolbox Items** dialog.

Wherever this documentation refers to Toolbox Items, it needs to be interpreted depending on whether you are working with a Windows Forms or a WPF project, as described below.

If the needed components do not show in the **Toolbox**: See **Troubleshooting Visual Studio Toolbox (Section 14.2)**.

Windows Forms

In Windows Forms projects, the Toolbox Items (live binding components) appear right in Visual Studio's **Toolbox** under the "QuickOPC" tab:

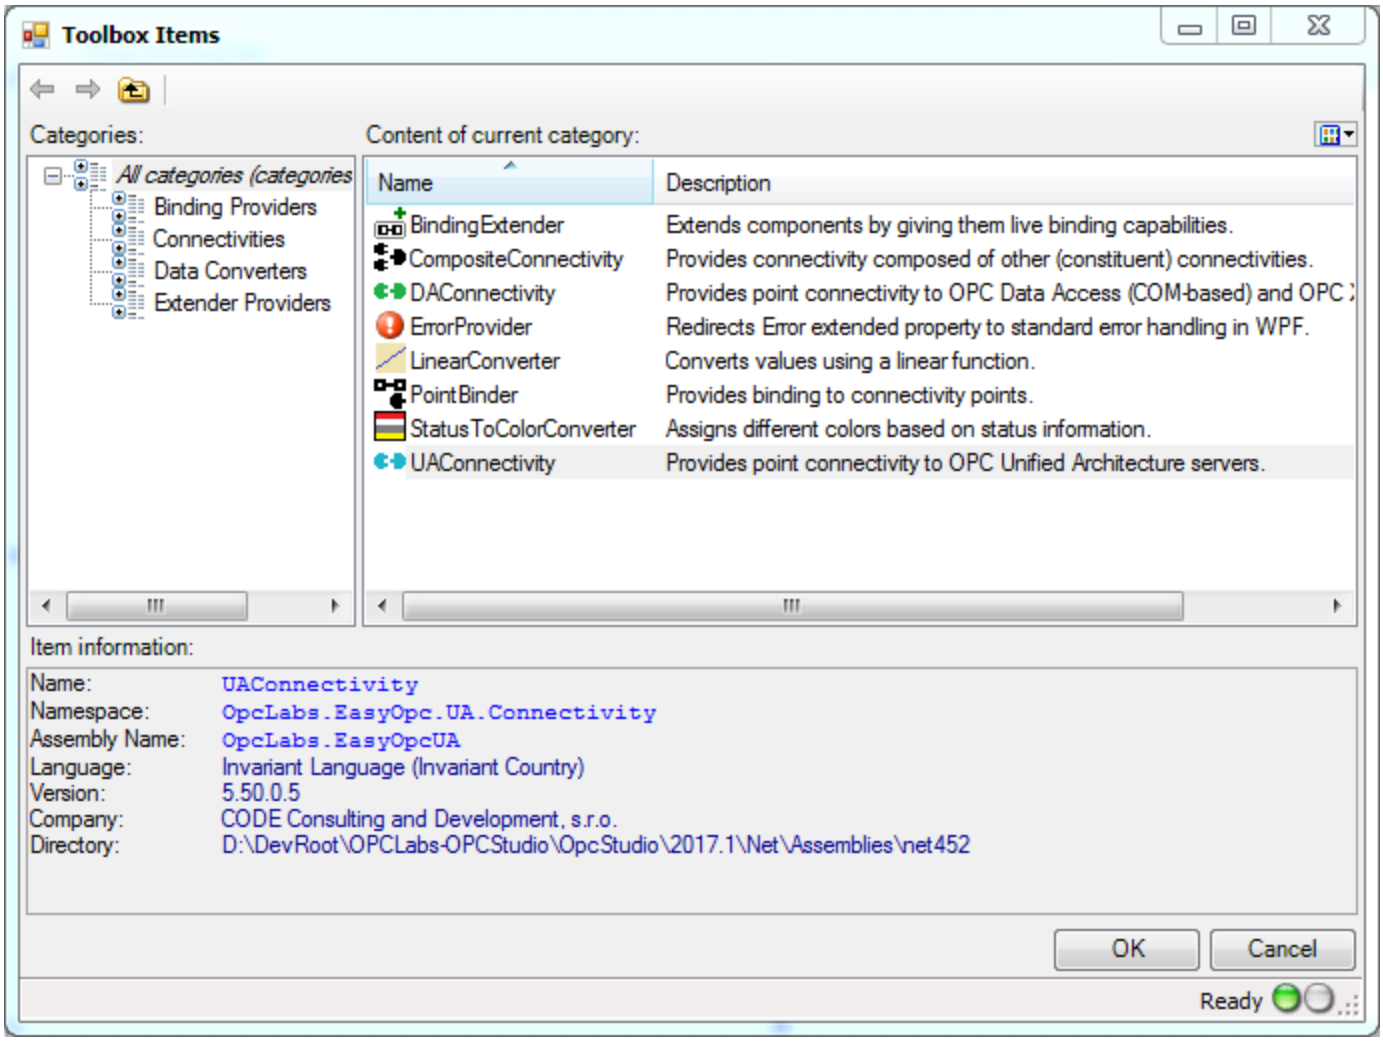


Note that in Windows Forms, the Toolbox show both visual, and non-visual items.

Note: For the components to be visible in the toolbox, your project needs to be set to target the.NET Framework 4.7 or later.

WPF

In WPF projects, you need to first invoke the **Component Tray** dialog in order to work with the items on the component tray. You can then add components from Toolbox Items to the tray by pressing the Add button. A **Toolbox Items** dialog will appear:



The **Toolbox Items** dialog in WPF shows only nonvisual components applicable to WPF projects.

Common Concerns

In order to work with live binding and enable it in your project, you need to place the desired component from the toolbox items to the component tray of your form (container) or window.

Because the PointBinder must always be used with BindingExtender in order to be usable, the toolbox item for the PointBinder uses a special logic, and assures that there is an associated BindingExtender in the container (usually, a form) as well. When you place a PointBinder onto the component tray, we first check whether some BindingExtender already exists in the container, and if so, we configure the newly created binder component to use it (by setting its BindingExtender property). If there is no BindingExtender component on the component tray, we create a new one, and configure the new binder to use it as well.

Similarly, any connectivity component is normally used with the PointBinder. Placing DAConnectivity, UAConnectivity or CompositeConnectivity onto the component tray takes with (or configures) a PointBinder as well.

As a result, in most cases you can simply “forget” about the need to place the BindingExtender or the PointBinder onto the component tray – simply place the connectivity (DAConnectivity, UAConnectivity or CompositeConnectivity) from the toolbox items onto the component tray, and the rest will be taken care of. Just remember that you should not delete the BindingExtender or the PointBinder from your form (window), even though you have not explicitly placed it there.

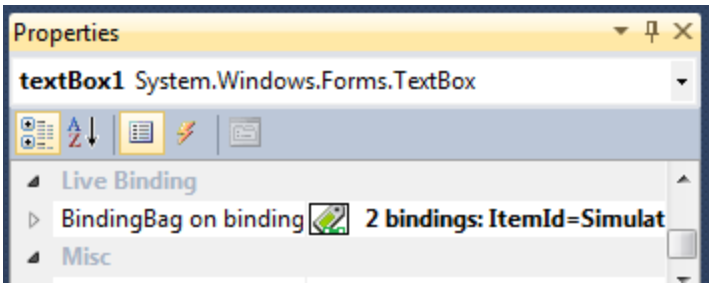
5.3.1.4.4 Extender Properties

The binding extender (BindingExtender component) has the ability to extend the properties of existing controls. When a binding extender is in the container (is placed onto the component tray), each eligible control receives new properties. Some of these properties are hidden, the remaining appear under the “Live Binding” category in the Properties window for each extended control.

In This Topic

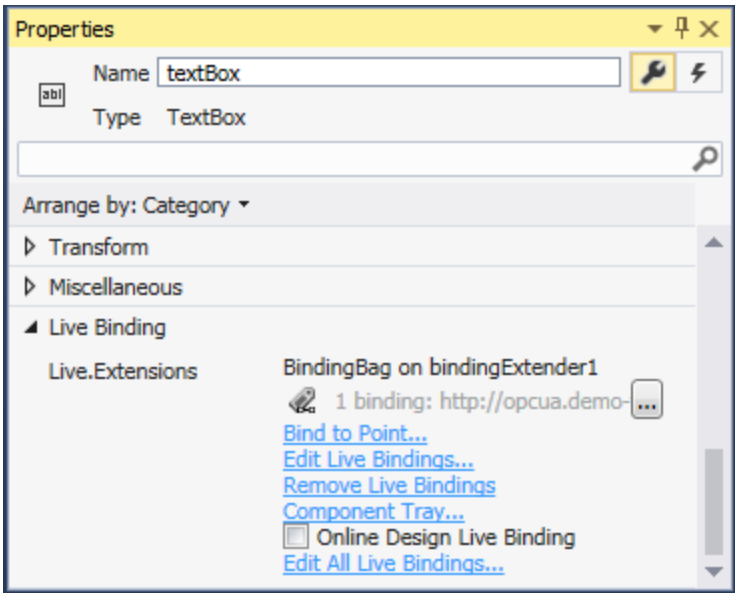
Windows Forms

In Windows Forms projects, extender properties are usually shown in the **Properties** window under the Live Binding category:



WPF

Similarly to Windows Forms projects, extender properties in WPF are usually shown in the **Properties** window under the Live Binding category, but a bit differently:



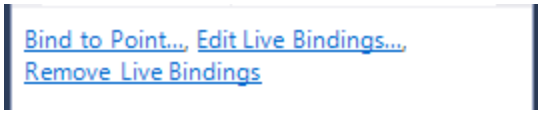
Common Concerns

The BindingBag extender property contains the binding bag, i.e. the collection of live bindings on the control. The designer shows the number of bindings contained in the bag. If they have the same type, it also shows a corresponding icon for that binding type, and if they have the same source, it also shows what the source is.

5.3.1.4.5 Designer Commands

Placing a BindingExtender onto a component tray automatically extends the set of commands (so-called Designer Verbs) available for other components (controls) in the same container (usually, a form in Windows Forms, or a window in WPF).

The new commands are available in the context menu for each component (when you right-click on the component or control), and also in the property grid for that component (in the **Properties** window), when the component is selected:



In Windows Forms projects, if you do not see the commands in the **Properties** window, right-click in the property grid area, and make sure that the "Commands" menu item is checked.

Following designer commands are available:

Bind to Point:

Allows you to select a point (OPC-DA item, property, OPC UA node/attribute) first, and then binds its value to the selected control, for the Read and Subscribe operations. It binds to the default target member of the control.

You can subsequently use the "Edit Live Bindings" command if you want to modify the target member selection, or other characteristics of the binding.

Edit Live Bindings:

Invokes the Binding Collection Editor, allowing you to add, remove, and modify bindings on the selected control.

Remove Live Bindings:

Removes all live bindings currently defined on the selected control.

When repeatedly using any of the "Bind to" commands, the browsing continues at the recently selected node. This allows for easier binding of multiple components to a set of related nodes.

When repeatedly using any of the "Bind to" commands, the browsing dialog retains its location and size between invocations, making it easy for the user to position it conveniently during the design session.

5.3.1.4.6 Binding Collection Editor

The binding collection editor allows adding, removing, and modifying bindings. It is usually invoked to work on bindings for a specified control, but it can also be used to work on bindings of all controls in a container (a form in Windows Form, or a window in WPF, typically). It is basically an editor for Binding Bags.

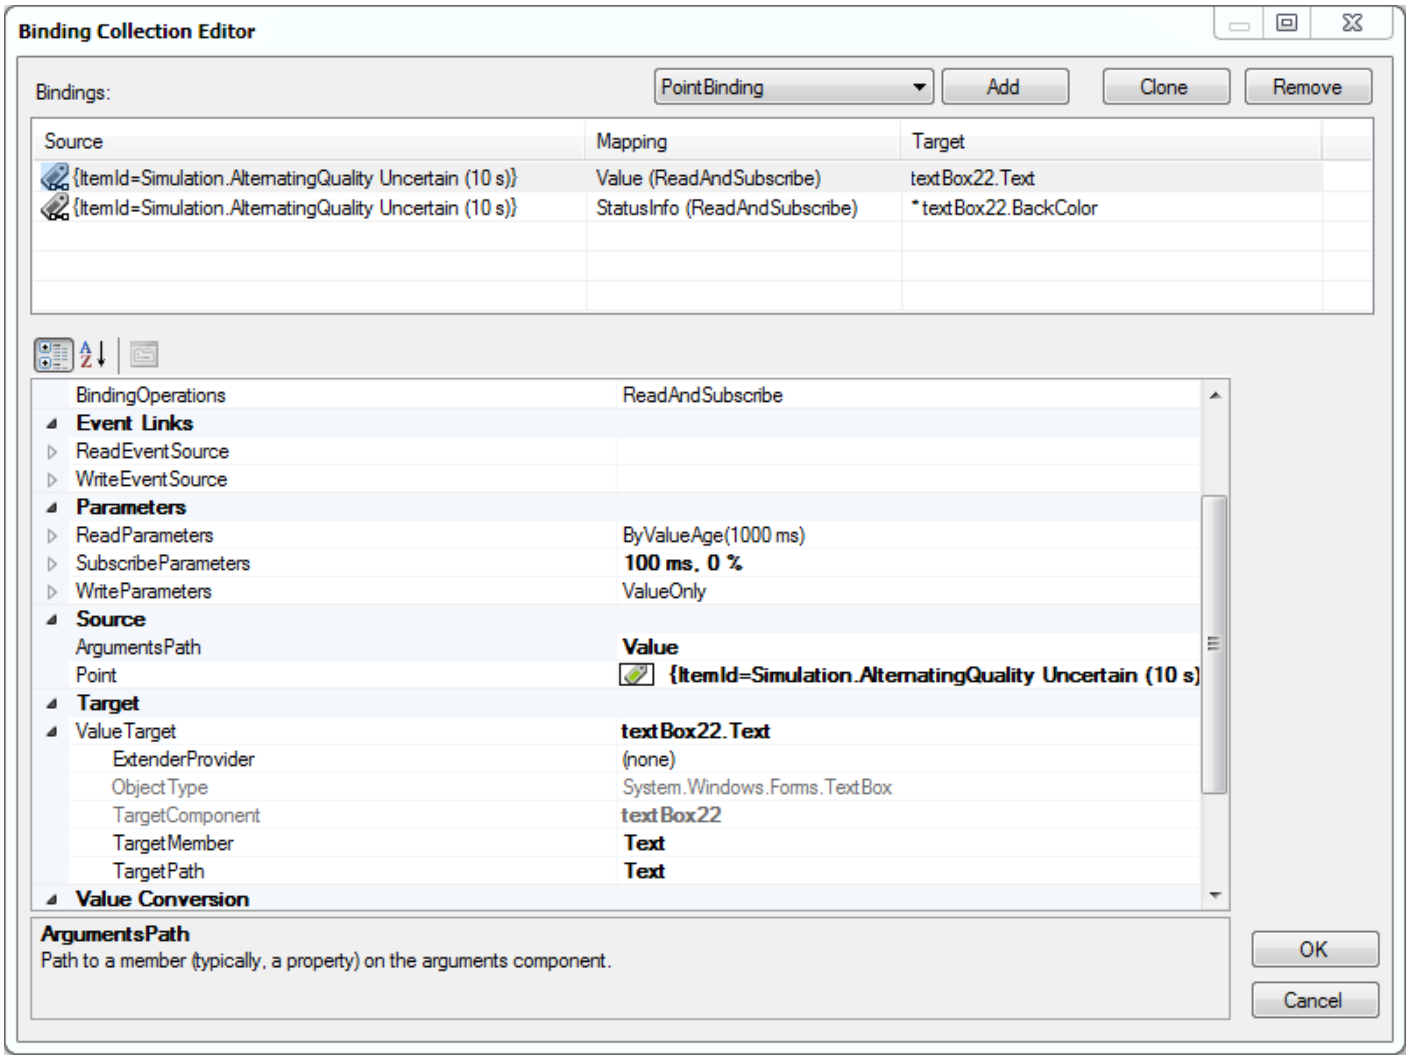
To show the binding collection editor for a specific control, you can either:

a. Right-click on the control, and select "Edit Live Bindings..." from the context menu.
b. Select the control, and then click on "Edit Live Bindings..." command in the Properties window (if commands are not visible in the property grid, right-click on it and check the Commands menu item).
c. Select the control, and in the Properties window, find the BindingBag property (under the Live Binding category). Select this property, and then click the small "..." button on the right side.

Note: If you do not see any of the above commands, the likely reason is that you have not placed the BindingExtender component on the form.

To show the binding collection editor for all controls on a Windows form, select the BindingExtender component, and in the Properties window, find the ComposedBindingBag property. Select this property, and then click the small "..." button on the right side.

When invoked, the binding collection editor looks similar to this:



The “Bindings” list displays all bindings in the collection, and the most important information about them (the source, the binding operations, and the target of the binding). Selecting any row in the “Bindings” list displays the properties of the selected binding in the “Binding properties” property grid. You can then view and modify the detailed properties of the binding in the property grid.

> You can also view and modify the design-time properties of each binding: The name (Name) used in code to identify the object, whether a member variable will be generated for the component (GenerateMember), and the visibility level of the object (Modifiers).

There are also following commands available in the binding collection editor:

Add:

Creates a new binding of the selected type, and adds it to the binding collection. Before pressing Add, you need to select the desired type of binding in the drop-down list left to the Add button.

The newly created binding gets some of its parameters from the templates defined on the binder or the connectivity component. If you create many similar bindings (such as always referring to the same OPC Server), you can save yourself lots of work by pre-filling the template with parameters that you commonly use.

Clone:

Create a duplicate of the selected binding (or bindings). This can be useful when you have made the main binding on the control, usually with ArgumentsPath of Value, and you want to extend it further, e.g. by adding a tooltip, or change the background color. In this case you need to bind to the same source and using the same parameters, and you will be changing just the arguments path and the binding target.

Remove:

Remove the selected binding (or bindings).

OK:

Confirms the changes made to the bindings in the dialog, and closes the dialog.

Cancel:

Dismisses any changes made to the bindings in the dialog, and closes the dialog.

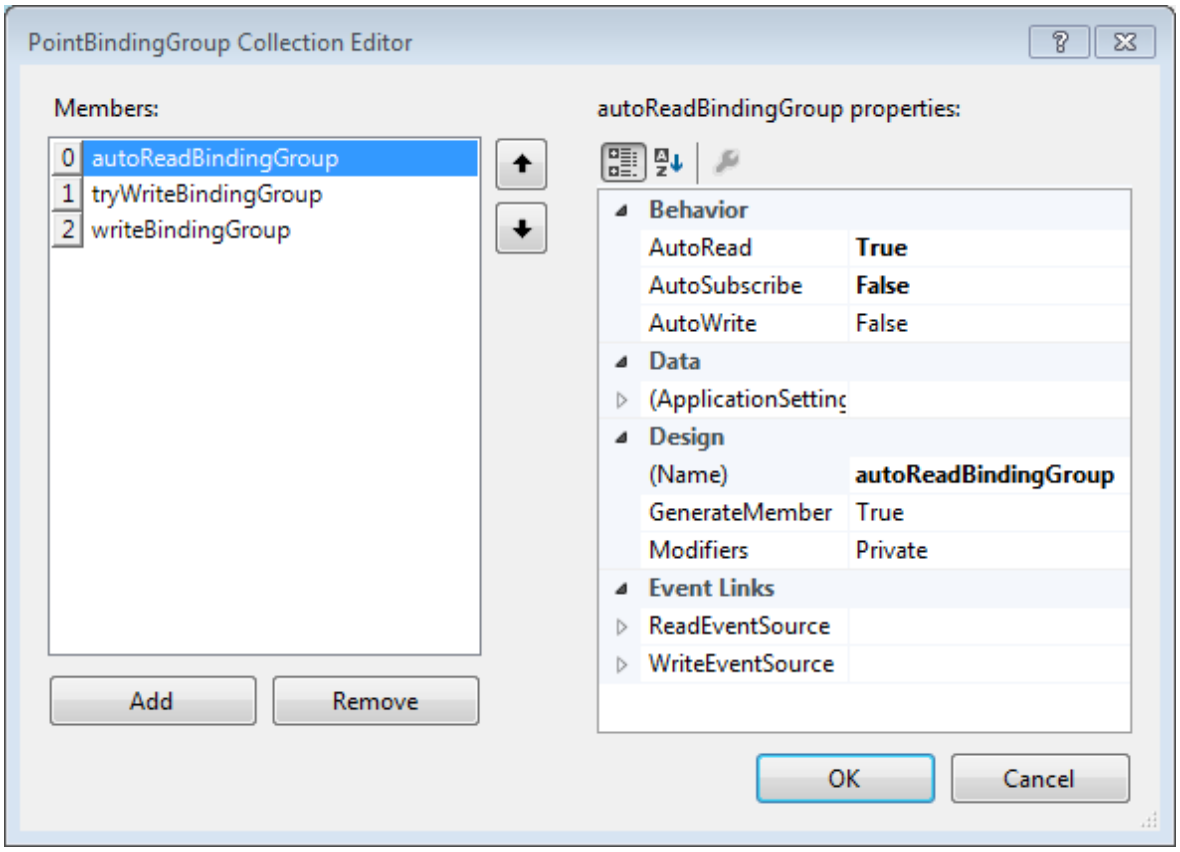
All changes that you make to the bindings in the binding collection editor are temporary, until you press OK. You can revert to the original state by pressing Cancel at any moment.

Note: Emptying the ValueTarget.TargetComponent of any binding will effectively remove the binding from the binding collection when the dialog changes are confirmed. This is because bindings must always be associated with their target.

5.3.1.4.7 Binding Group Collection Editor

The binding group collection editor allows adding, removing, and modifying the Binding Groups. To show the binding group editor, select the PointBinder component placed on your component tray, and in the Properties window (or, in WPF in the property grid next to the Components list), select its BindingGroups property. Then, click the small "..." button on the right side.

When invoked, the binding group collection editor looks similar to this:



Note that the default binding group does not appear in the BindingGroups collection. It is a separate object that you can edit directly, as the DefaultBindingGroup property of the PointBinder component.

5.3.1.4.8 Online Design

The live binding model includes an Online Design feature that allows you to explore and verify most aspects of the configured live bindings without building and running your application. You can see the binding truly live – i.e. while still designing in Visual Studio, the binding operations can be performed. This means that when you configure e.g. a Read or Subscribe operation with your binding, you can pre-view live OPC data on your form, and verify that the binding works as intended.

In This Topic

WPF

Initially, the Online Design mode is turned off. In order to control the Online Design mode, you can either right-click on the BindingExtender component on your component tray, and select “Design Online” or “Design Offline” command from its context menu (Windows Forms only), or you can select the BindingExtender component in the component tray first, and then use the same commands in Properties windows or property grid next to the Components list (provided that commands are enabled in the property grid; if not, right-click on it and check the Commands item).

Because the live binding makes modifications to property values of components in your program, be aware that the online design has the same effect. If you do not want the values resulting from online design to persist in your project, you need to refrain from saving the changes made by online design.

When the design is made online, it can be much more demanding on computer resources, because each value update causes value changes that need to be reflected by the designer, regenerating code and making other changes in the environment. In order to maintain responsiveness of the development environment, the update rate in the online design mode is limited. Even if you set the update rate to a fast value, you may get slower update rates during the design.

WPF

In WPF (as opposed to Windows Forms), if you make a change to binding properties while the Online Design is turned on, the changed are not immediately picked up. You need to turn the Online Design off and on again.

In WPF, screen updates for Online Design are performed on background, with low priority. As a result, it is possible that not all updates always occur, especially if you have many bound controls.

In WPF, we try to prevent the changed property values (from Online Design) be stored back into the XAML, but depending on circumestances, it is not always 100% reliable.

5.3.1.5 Live Binding Details

This chapter describes more advanced workings of the live binding, and some internals that help in understanding it.

5.3.1.5.1 How the Binding Extender Automatically Goes Online and Offline

The BindingExtender component has two configurable event links that allow it to automatically go online or offline:

- OnlineEventSource: Event triggered by this source puts the binding extender into the online mode.
- OfflineEventSource: Event triggered by this source puts the binding extender into the online mode.

Depending on the kind of project, Live Binding uses following rules to determine the default settings of these properties:

- In Windows Forms, when you initially place the BindingExtender component onto a Windows form by dragging it from a Toolbox, its OnlineEventSource is set to the Form's Shown event, and its OfflineEventSource is set to the Form's FormClosing event.
- In WPF, when you initially place the BindingExtender component onto a component tray by adding it from Toolbox Items, its OnlineEventSource is set to the root object's Loaded event, and its OfflineEventSource is set to the root object's Closed event. The root object is normally the window being designed.

The effect of this configuration is such that during runtime, the binding extender is automatically online while the form or window is open, and it also goes offline when the form or window closes.

This default setting makes it easy to create forms that are "live" (online) without further coding or configuration. If you, however, want to have control over the process, you can clear these event sources, and use the BindingExtender's Online property to set or reset the online state.

5.3.1.5.2 What Happens When the Binding Extender Is Set Online or Offline

When the binding extender is set to online (i.e. when its Online property is set to 'true'), following steps are performed internally:

1. Each configured binding makes its “links”, i.e. hooks the handlers for its configured event sources. For example, the PointBinding-s have ReadEventSource and WriteEventSource, so if they are configured, the binding will link the events with handlers that perform Read or Write operation on the point binding.
2. All binding groups perform their configured automatic operations. For PointBindingGroup-s, this means that:
    a. If AutoRead property is set, the Read operation is executed for all PointBinding-s that have Read included in their BindingOperations property (this includes “Get” of OPC-DA properties).
    b. If AutoSubscribe property is set, the Subscribe(true) operation is executed for all PointBinding-s that have Subscribe included in their BindingOperations property.
3. All binding groups make their “links”, i.e. hook the handlers for their configured event sources. For PointBindingGroup-s, this means that the events for ReadEventSource and WriteEventSource will be linked with handlers that perform Read or Write operation on the binding group.
4. The OnlineChanged event is raised on the BindingExtender.

When setting the binding extender to offline, the above steps are (roughly said) reversed. There are, however, differences in Step 2: For PointBindingGroups-s, the Read operations are not executed; instead, if AutoWrite property is set, the Write operation is executed for all PointBinding-s that have Write included in their BindingOperations property. Also, if AutoSubscribe property is set, the Subscribe(false) operation is executed (i.e. unsubscribe, instead of subscribe).

5.3.1.5.3 What Happens When a Binding Operation Method Is Called

When any operation is invoked either automatically (with help of configures event sources), or programmatically, the live binding system first determines the set of bindings involved in the operation, and then executes the requested operation.

For operations invoked directly on the binding, the operation is performed on this single binding.

For operations invoked on some binding group, the group first determines the bindings that belong to it. It then performs the operation together on all bindings in this group.

5.3.1.5.4 Programmatic Access to Live Binding

Below are the most commonly needed programmatic actions:

- To set the binding extender (all bindings on it) to online or offline from your code, set its Online property to true or false. The binding extender is a component placed on your form, so you can refer to it by its name.
- To execute the Read or Write operation on concrete binding, call the PointBinding’s ExecuteRead or ExecuteWrite method. Note that although the individual binding do not appear on the design surface (of the form) or on the component tray, they are still components of your form, and you can refer to individual bindings by their name (as of now, you cannot change the name from the binding collection editor, so you need to look it up in the designer-generated code, and either use it as is, or rename manually).
- To execute any of the operations on a concrete binding group (for all binding in that group that have that operation allowed), call a corresponding method on the PointBindingGroup object. The binding groups do not appear on thecomponent tray (of the form or window), but they are still components that belong to your form or window, and you can refer to them by their name. The name of the binding group can be viewed or modified in the Binding Group Collection Editor. The method names are PointBindingGroup.ExecuteRead, ExecuteSubscribe and ExecuteWrite. The ExecuteSubscribe has a bool argument that determines whether you want to subscribe or

unsubscribe.

You can also override some of the error handling in live binding (see **Error Handling in Live Binding (Section 5.3.1.5.5)**).

5.3.1.5.5 Error Handling in Live Binding

There are several types of errors that can occur in relation to live binding, and they are treated differently.

I. When you configure the live binding in the designer, there may be one or more *binding errors*, caused by improper configuration. When this happens, the designer displays a form that lists all the binding errors detected.

   You can press the "Details..." button to view the details of the binding errors listed on the form.

   The binding errors are caused by BindingException-s during the design, and are generally "benign", meaning that you can continue your design work, but you'd better fix the errors, otherwise they can cause more serious errors during runtime.

   Examples of such binding errors are:

   - A binding where the value target has no TargetComponent specified.
   - Member linking error: The specified target member does not exist.
   - Member linking error: Cannot determine the data type of the target member.

   In the runtime, binding errors are reported by the BindingExtender.BindingErrors event. Unless you hook your own handler to this event, they are silently ignored.

II. When the binding extender is set online or offline, there can also be *event linking errors*. They are similar to binding errors in that they are caused by improper configuration – this time, an improper configuration of some of the event sources used to automatically trigger the operations.

   Unless you decide to handle them, event linking errors are silently ignored both during design-time and in runtime. For event sources defined on the binding extender, any event linking error is signaled by the BindingExtender.EventLinkingFailure event. For event sources defined on the binder component (PointBinder, usually), its binding groups or its bindings, any event linking error is signaled by the BinderBase.EventLinkingFailure event.

III. When a target could not be updated with a new value, an *update failure* occurs. Unless you decide to handle them, update failures are silently ignored both during design-time and in runtime. Each failure is signaled by the PointBinder.UpdateFailure event. The event notification contains an Exception indicating the cause of the update failure, and a reference to the related binding. You can hook your event handler to this event if you need some action be performed in such case.

   There may be various reasons for update failures; the most common are *target access errors*. They happen when the live binding encounters a failure accessing your objects (binding targets). For example, setting or getting a property on your object may throw an exception, and such exception will be caught. Target access error is represented by an instance of TargetAccessException in an update failure.

Errors that originate in the binding source, such as OPC item or OPC property, are considered a completely separate issue. For example, the OPC server may be shut down, or the item ID might have changed name and is no longer accessible, or its value just has a bad "quality". Such errors are treated as just another data to be transferred by the binding. There are arguments (see Arguments and Results) such as Exception or ErrorId that allow you to set up members on your objects that will receive error information in case of errors that originate in the binding source.

5.3.1.5.6 Usage Guidelines (Live Binding)

Configuration and Programming

Below are some pieces of advice that may help you configure and use the live binding properly:

- If operations need to be performed together, they must be assigned to the same binding group and invoked on the group. Let's describe the wrong approach first: When the user presses a button, you want to grab values from several controls on the form, and write them to various OPC items. You configure the WriteEventSource on each binding to the Click event of the Button. Well, while this "kind of" works, it is very ineffective approach, because each binding will be handled separately, and the OPC writes will be executed one by one, sequentially. The proper approach is to create a binding group for this purpose, set all bindings involved in the "write" to be members of this binding group, and then set the WriteEventSource just once, on the binding group itself. This way, the binding group will attempt to write all values into their corresponding OPC items using a single call with multiple items in it.
- Remember to always set the BindingExtender back to offline mode. This guideline only applies if you are controlling the BindingExtender-s Online property in a way that differs from the default described in **How the Binding Extender Automatically Goes Online and Offline (Section 5.3.1.5.1)**. In such case, you need to be aware that while the BindingExtender is online mode, there are event handlers set up that may prevent the normal application shutdown. Basically, by setting the Online property of BindingExtender to 'true', you indicate that for whatever reason, you are interested in being connected to the binding targets – and you have to explicitly set it back to false in order to indicate that this is no longer needed.

Combination with Imperative Programming Model

For more advanced tasks, you may want to combine the Live Binding model with the **Imperative Programming Model (Section 5.1)**. Such combination is perfectly possible and supported.

When doing so, consider the fact that Live Binding uses its own, "isolated" client objects (such as EasyDAClient or EasyUAClient). When you create instances of the client objects in your own code, your code will have separate connections (sessions) from those used in the Live Binding. This may be fine, but can cause issues in some cases (e.g. when the target OPC Server is an embedded server with limited number of concurrent sessions).

In order to prevent this from happening, you can "borrow" the client object from the Live Binding, and use it in your code. To do so, call the GetClient methods on the DAConnectivity or UAConnectivity component that you already have for the Live Binding. The method returns an IEasyDAClient (or IEasyUAClient) interface, and you can use it to perform any necessary operations through imperative programming.

5.3.1.6 Typical Binding Scenarios

The live binding model is very powerful in terms of what can be achieved without any manual coding. In order to configure it right, however, you need to know how, and understand a little about the internal workings of live binding. The scenarios described in this chapter are designed just for that – to give instructions that will guide you through configuring the live binding for typical usages.

Each scenario contains a description of its purpose, and step by step instructions explaining how to configure it.

You should be able to use these scenarios both as a “catalog”, a reference to choose from and follow the steps, and as a learning tool: If you try several scenarios, you will get a feeling of how to configure the live binding for proper behavior.

Many of the scenarios listed here are also demonstrated live in the “Live Binding Demo” applications that are installed with the product. For OPC Data Access (OPC-DA), its source code is contained in the WindowsForms\LiveBindingDemo project. For OPC Unified Architecture (OPC-UA), its source code is contained in the WindowsForms\UALiveBindingDemo project.

5.3.1.6.1 Automatic Subscription (With the Form or Window)

This is the default behavior. The binding is online while the form or window is open. You can bind to all types of components and controls. You can bind to any property or field. You can also bind to some methods and events.

How to configure this feature for OPC-DA:

If you have not done so yet, place the DAConnectivity component onto the component tray of the form or window (this is a common step for all binding tasks).

Use the "Bind to Point" command on the target control, and select the source OPC server and OPC item.

That's it. You can verify the result immediately, without recompiling your application, by using the "Design Online" command on the BindingExtender component.

How to configure this feature for OPC-UA:

If you have not done so yet, place the UAConnectivity component onto the component tray of the form or window (this is a common step for all binding tasks).

Use the "Bind to Point" command on the target control, and select the source OPC-UA server and OPC node.

That's it. You can verify the result immediately, without recompiling your application, by using the "Design Online" command on the BindingExtender component.

5.3.1.6.2 Automatic Read (On Form or Window Load)

OPC-DA item values (or OPC-UA node attributes) can be also read once, when the form or window loads.

How to configure this feature for OPC-DA:

On a PointBinder, edit the BindingGroups collection, "Add" a new binding group, set its AutoRead property to True, and make sure that its AutoSubscribe property is set to False.

On a TextBox (or other control), use "Bind to Point" command and select the OPC item you want to read. Then, use the "Edit Live Bindings" command, and set the BindingGroup property of the item binding to the binding group you have created earlier. The Read operation is automatically executed for all item bindings in this group when the form loads.

How to configure this feature for OPC-UA:

On a PointBinder, edit the BindingGroups collection, "Add" a new binding group, set its AutoRead property to True, and make sure that its AutoSubscribe property is set to False.

On a TextBox, use "Bind to Point" command and select the OPC-UA node you want to read. Then, use the "Edit Live Bindings" command, and set the BindingGroup property of the data binding to the binding group you have created earlier. The Read operation is automatically executed for all data bindings in this group when the form loads.

5.3.1.6.3 Read On Custom Event

For example, clicking the Read button will execute the operation and read the OPC item value into the text box.

How to configure this feature for OPC-DA:

On a TextBox (or other control), use "Bind to Point" command and select the OPC item you want to read (alternatively, use "Edit Live Bindings" command, "Add" a PointBinding, and configure its point's ServerDescriptor and ItemDescriptor).

Then, use the "Edit Live Bindings" command, and for BindingOperations property, leave just Read checked (and uncheck the Subscribe). In order to have the Read invoked when the button is pressed, set the ReadEventSource.SourceComponent to the Button control; the SourceMember of the ReadEventSource will be automatically set to the Click event. This causes the Click on the Button execute the Read operation, i.e. obtain the OPC item value and store it into the TextBox.

Note: In order to read multiple items at once on a custom event, it is suggested that you set up a binding group under the PointBinder, assign the bindings to the group, and link the ReadEventSource just once, on the binding group.

How to configure this feature for OPC-UA:

On a TextBox, use "Bind to Point" command and select the OPC-UA node you want to read (alternatively, use "Edit Live Bindings" command, "Add" a PointBinding, and configure its EndpointDescriptor and NodeDescriptor).

Then, use the "Edit Live Bindings" command, and for BindingOperations property, leave just Read checked (and uncheck the Subscribe). In order to have the Read invoked when the button is pressed, set the ReadEventSource.SourceComponent to the Button control; the SourceMember of the ReadEventSource will be automatically set to the Click event. This causes the Click on the Button execute the Read operation, i.e. obtain the OPC-UA node value and store it into the TextBox.

Note: In order to read multiple nodes at once on a custom event, it is suggested that you set up a binding group under the PointBinder, assign the bindings to the group, and link the ReadEventSource just once, on the binding group.

5.3.1.6.4 String Formatting

All standard .NET formatting features can be used to specify how the OPC values should be displayed.

How to configure this feature:

Bind the OPC-DA item (or OPC-UA node attribute) to the TextBox or similar control as usually.

Then, use the "Edit Live Bindings" command on the control, and set the StringFormat property on the item binding as needed, using all standard .NET formatting capabilities. {0} in the formatting string represents the value to be formatted. For example, {0:F3} means a floating point value formatted with 3 decimal places.

5.3.1.6.5 Change Color According to Status

Values can be converted in both directions by IDataConverter objects. For example, StatusToColorConverter provides a color value based on operation status, such as a yellow background when quality is Uncertain.

How to configure this feature:

Place the StatusToColorConverter component (from the toolbox items) onto the component tray. Bind the OPC-DA item (or OPC-UA node attribute) to your control as usually.

Then, use the "Edit Live Bindings" command, "Clone" the existing binding, and change the cloned binding as follows: Set the ArgumentsPath to StatusInfo. Set the ValueTarget.TargetMember to the BackColor (in Windows Forms), Background (in WPF), or other suitable property of your control. For the Converter property, select the StatusToColorConverter you have placed to the form earlier. This will cause the status information from the OPC item be converted to one of

configurable colors, and change the background color of the control appropriately.

5.3.1.6.6 ToolTip and Other Extenders

In general, Live Binding supports extender providers and extender properties both in Windows Forms and in WPF. The procedure described below for WIndows Forms, however, is not usable with WPF, because in WPF. tooltips are not implemented using an extender provider, but are instead a property right on the control level.

In This Topic

Windows Forms

You can bind to properties made available by extender providers, such as ToolTip. Hovering over the control associated with the ToolTip then allows the user to see more details about the value.

How to configure this feature for OPC-DA:

Drag the ToolTip extender (standard Microsoft component), or other extender provider you need, from the toolbox to the form. Configure the binding in a usual way.

Then, use the "Edit Live Bindings" command, "Clone" the existing binding, and change the cloned binding as follows: Set the ValueTarget.ExtenderProvider to the ToolTip (extender provider) component on your form, and set the ValueTarget.TargetMember to the Tooltip member. Set the ArgumentsPath to Vtq (or Timestamp, Quality, or whatever you'll want to be displayed in the tooltip). This will cause the additional information from the OPC item be displayed by the ToolTip extender provider for the control.

How to configure this feature for OPC-UA:

Drag the ToolTip extender (standard Microsoft component), or other extender provider you need, from the toolbox to the form. Configure the binding in a usual way.

Then, use the "Edit Live Bindings" command, "Clone" the existing binding, and change the cloned binding as follows: Set the ValueTarget.ExtenderProvider to the ToolTip (extender provider) component on your form, and set the ValueTarget.TargetMember to the Tooltip member. Set the ArgumentsPath to AttributeData (or SourceTimestamp, ServerTimestamp, StatusCode, or whatever you'll want to be displayed in the tooltip). This will cause the additional information from the OPC-UA be displayed by the ToolTip extender provider for the control.

WPF

How to configure this feature:

Configure the binding in a usual way.

Then, use the "Edit Live Bindings" command, "Clone" the existing binding, and change the cloned binding as follows: Set the ValueTarget to the Tooltip member. Set the ArgumentsPath to AttributeData (or SourceTimestamp, ServerTimestamp, StatusCode, or whatever you'll want to be displayed in the tooltip). Set the StringFormat property on the data binding to {0} or as needed. Note that the displayed tooltip is not dynamically updated when StringFormat is not set.

5.3.1.6.7 Display Errors with ErrorProvider

Windows Forms

The standard ErrorProvider extender is useful for displaying OPC operation error icons, with tooltips.

How to configure this feature:

Drag the ErrorProvider extender (standard Microsoft component) from the toolbox to the form. Configure the binding in a usual way.

Then, use the "Edit Live Bindings" command, "Clone" the existing binding, and change the cloned binding as follows: Set the ArgumentsPath to ErrorMessage. Set the ValueTarget.ExtenderProvider to the ErrorProvider component on your form, and set the ValueTarget.TargetMember to the Error member. All in all, this will cause the error message from the OPC-DA item (or OPC-UA node attribute) be stored into the error text displayed by the ErrorProvider for the control.

Note: If you configure this with explicit Read or Write operations (not with Subscribe), you need to set up a binding group, assign related bindings to the same group, and have the operation invoked on a binding group.

WPF

Configure the binding in a usual way.

Place the ErrorProvider extender (this is not a standard Microsoft component) from the toolbox items onto the Component Tray. Configure the binding in a usual way.

Then, use the "Edit Live Bindings" command, "Clone" the existing binding, and change the cloned binding as follows: Set the ArgumentsPath to ErrorMessage. Set the ValueTarget.ExtenderProvider to the ErrorProvider component on your form, and set the ValueTarget.TargetMember to the Error member. All in all, this will cause the error message from the OPC-UA be stored into the error text displayed by the ErrorProvider for the control.

Note: If you configure this with explicit Read or Write operations (not with Subscription), you need to set up a binding group, assign related bindings to the same group, and have the operation invoked on a binding group.

Tip: The standard Validation.ErrorTemplate simply displays a red rectangle around control, but without the error text. In order to display the error text as well, you need to use styles - define your own Validation.ErrorTemplate in XAML <Window.Resource>. Then, set Validation.ErrorTemplate="{StaticResource ErrorTemplate}" for the control.

ErrorTemplate example (indicates the error by a red circle with an exclamation mark, and the error text):

```
<Window.Resources>
        <Style x:Key="BlinkedEllipse" TargetType="{x:Type Ellipse}">
            <Style.Triggers>
                <EventTrigger RoutedEvent="Ellipse.Loaded">
                    <EventTrigger.Actions>
                        <BeginStoryboard>
                            <Storyboard>
                                <DoubleAnimation Storyboard.TargetProperty="Opacity"
From="1" To="0" Duration="0:0:0.5" AutoReverse="True" RepeatBehavior="3x"/>
                            </Storyboard>
                        </BeginStoryboard>
                    </EventTrigger.Actions>
                </EventTrigger>
            </Style.Triggers>
        </Style>
        <ControlTemplate x:Key="ErrorTemplate">
```

```
            <DockPanel LastChildFill="True">
                <Grid Width="16" Height="16" DockPanel.Dock="Right">
                    <Ellipse Width="16" Height="16" HorizontalAlignment="Center"
VerticalAlignment="Center" Stroke="Black" StrokeThickness="1" ToolTip="{Binding
AdornedElement.(Validation.Errors)[0].ErrorContent, ElementName=ErrorAdorner}" Style="
{StaticResource BlinkedEllipse}">
                        <Ellipse.Fill>
                            <LinearGradientBrush StartPoint="0,0" EndPoint="1,1" >
                                <GradientStop Color="White" Offset="0" />
                                <GradientStop Color="Red" Offset="1.0" />
                            </LinearGradientBrush>
                        </Ellipse.Fill>
                    </Ellipse>
                    <TextBlock Foreground="White" FontWeight="Heavy" FontSize="12"
HorizontalAlignment="Center"
                                            VerticalAlignment="Center"
TextAlignment="Center"
                        ToolTip="{Binding AdornedElement.(Validation.Errors)
[0].ErrorContent, ElementName=ErrorAdorner}"
                                            Text="!"/>
                </Grid>
                <AdornedElementPlaceholder x:Name="ErrorAdorner" />
            </DockPanel>
        </ControlTemplate>
</Window.Resources>
```

Tip: If ErrorProvider is used in binding for control that is inside TabItem or GroupBox, then <AdornerDecorator> should be used, see:

```
<GroupBox>
    <AdornerDecorator>
        <Grid>
            <TextBox> <!-- TextBox with LiveBinding using ErrorProvider !-->
            </TextBox>
        </Grid>
    </AdornerDecorator>
</GroupBox>
```

5.3.1.6.8 Various Kinds of Binding

You normally bind to the OPC value itself, but you can select from many other binding kinds, such as ErrorId, ErrorMessage, StatusInfo, (for OPC-DA) Timestamp, Quality, Vtq, or (for OPC-UA) ServerTimestamp, SourceTimestamp, AttributeData, StatusCode, etc.

How to configure this feature:

Bind the OPC item to your control as usually.

Then, use the "Edit Live Bindings" command on the control, and in the ArgumentsPath property, select the kind of binding you want.

5.3.1.6.9 Write Single Value on Custom Event

A value of control property is written to the associated OPC item when a specified event is triggered. For example, you can link the Write to the button click.

How to configure this feature:

On a TextBox (or similar control), use "Bind to Point" command and select the OPC-DA item (or OPC-UA node) you want to write to.

Then, use the "Edit Live Bindings" command, and for the BindingOperations options, select only "Write". In order to have the Write invoked when the button is pressed, set the WriteEventSource.SourceComponent to the Button control; the SourceMember of the WriteEventSource will be automatically set to the Click event. This causes the Click on the Button execute the Write operation, i.e. obtain the value from the control and write it into the OPC item.

5.3.1.6.10 Write Group of Values on Custom Event

In this scenario, multiple property values are gathered and written to their associated OPC items in a single operation, linked to a specified event – for example, a button click.

How to configure this feature for OPC-DA:

On a PointBinder, edit the BindingGroups collection, "Add" a new binding group, set its AutoSubscribe property to False, and set its WriteEventSource.SourceComponent to the button that should invoke the Write.

On each of the value controls involved, use "Bind to Point" command and select the OPC item you want to write. Then, use the "Edit Live Bindings" command, and for the BindingOperations options, select only "Write". Also, set the BindingGroup property of the item binding to the binding group you have created earlier. The Write operation will be executed for all item bindings in this group when the button is clicked.

How to configure this feature for OPC-UA:

On a PointBinder, edit the BindingGroups collection, "Add" a new binding group, set its AutoSubscribe property to False, and set its WriteEventSource.SourceComponent to the button that should invoke the Write.

On each of the value controls involved, use "Bind to Point" command and select the OPC-UA node you want to write. Then, use the "Edit Live Bindings" command, and for the BindingOperations options, select only "Write". Also, set the BindingGroup property of the data binding to the binding group you have created earlier. The Write operation will be executed for all data bindings in this group when the button is clicked.

5.3.1.6.11 Subscribe & Write

A control can reflect OPC value changes, and also write the updated values to the OPC server when modified by the user. For example, you can bind a TrackBar and a NumericUpDown controls to the same OPC item, and they will influence each other through OPC.

In This Topic

How to configure this feature:

On the target control, use "Bind to Point" command and select the OPC-DA item (or OPC-UA node) you want to bind to.

Then, use the "Edit Live Bindings" command, and for BindingOperations property, add a check next to the Write operation. In order to have the Write invoked when the control changes, set the WriteEventSource.SourceComponent to your control; the SourceMember of the WriteEventSource will be automatically determined, but you can change it, if you want to link to a different event.

Note: In OPC-DA, some controls will require you to set the ItemDescriptor.RequestedDataType so that the OPC value type matches the type of the target property.

Note: In OPC-UA, some controls or OPC-UA servers will require you to set the ValueTypeCode (under the WriteParameters property) so that the OPC-UA value type matches the type of the target property. It is also recommended to set the ValueTypeCode for performance reasons.

WPF

In WPF, there is no precise equivalent of the NumericUpDown control used in our Windows Forms example. The WPF Live Binding Demo uses styles to achieve a comparable result.

5.3.1.6.12 Display Write Errors

When the Write fails, you want the user be notified. One way to do this is with the standard ErrorProvider control. For example, if you attempt to write a value that is too large, an error icon appears, and the error message can be seen in the associated tooltip.

How to configure this feature:

On a PointBinder, edit the BindingGroups collection, "Add" a new binding group, set its AutoSubscribe property to False, and set its WriteEventSource.SourceComponent to the button that should invoke the Write.

Place the ErrorProvider extender from the toolbox items onto the component tray.

Configure the binding in a usual way. Use the "Edit Live Bindings" command, and for the BindingOperations options, select only "Write", and set the BindingGroup property of the item binding to the binding group you have created earlier. Then, "Clone" the existing binding, and change the cloned binding as follows: Set the ArgumentsPath to ErrorMessage. Set the ValueTarget.ExtenderProvider to the ErrorProvider component on your form, and set the ValueTarget.TargetMember to the Error member. This will cause the error message from the OPC item be stored into the error text displayed by the ErrorProvider for the control.

5.3.1.6.13 Get an OPC Property on Custom Event

You can bind to OPC-DA properties as well. For example, clicking on the Get button can obtain the value of the HighEU property.

Note: In OPC-UA Unified Architecture, there is no need for this – just use Read of any attribute of a node.

How to configure this feature:

On a TextBox, use "Bind to Point" command and select the OPC item and property you want to get (alternatively, use "Edit Live Bindings" command, "Add" a PointBinding, and configure its ServerDescriptor and PropertyDescriptor).

In order to have the Get invoked when the button is pressed, set the ReadEventSource.SourceComponent to the Button control; the SourceMember of the ReadEventSource will be automatically set to the Click event. This causes the Click on the Button execute the Get operation, i.e. obtain the OPC property value and store it into the TextBox.

5.3.1.6.14 Automatically Get an OPC Property (On Form Load)

The OPC-DA property value can also be obtained automatically when the form loads.

Note: In OPC-UA Unified Architecture, there is no need for this – just use Read.

How to configure this feature:

On a PointBinder, edit the BindingGroups collection, "Add" a new binding group, and set its AutoRead property to True.

On a TextBox, use "Bind to Point" command and select the OPC item and property you want to get. Then, use the "Edit Live Bindings" command, and set the BindingGroup property of the property binding to the binding group you have created earlier. The Get operation is automatically executed for all property bindings in this group when the form loads.

5.4 Reactive Programming Model

The reactive programming development model merges the world of Microsoft Reactive Extensions (Rx) for .NET with OPC. The Reactive Extensions (http://msdn.microsoft.com/en-us/data/gg577609.aspx) is a library to compose asynchronous and event-based programs using observable collections (data streams) and LINQ-style query operators.

OPC Data Client provides OPC-specific classes that implement the Rx interfaces. For example, you can easily create an Rx observable sequence with OPC-DA. OPC XML-DA or OPC-UA item changes, and process it further. Similarly, you can create an Rx observable sequence with OPC-A&E event notifications.

For complex event and stream processing that builds on top of the reactive programming model, see also

- **StreamInsight Option (Section 12.2)**
- **Installed Examples - Console - SimpleTrillApplication (Section 13.1.4.1.9)** (Microsoft Trill: https://github.com/microsoft/Trill)

The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

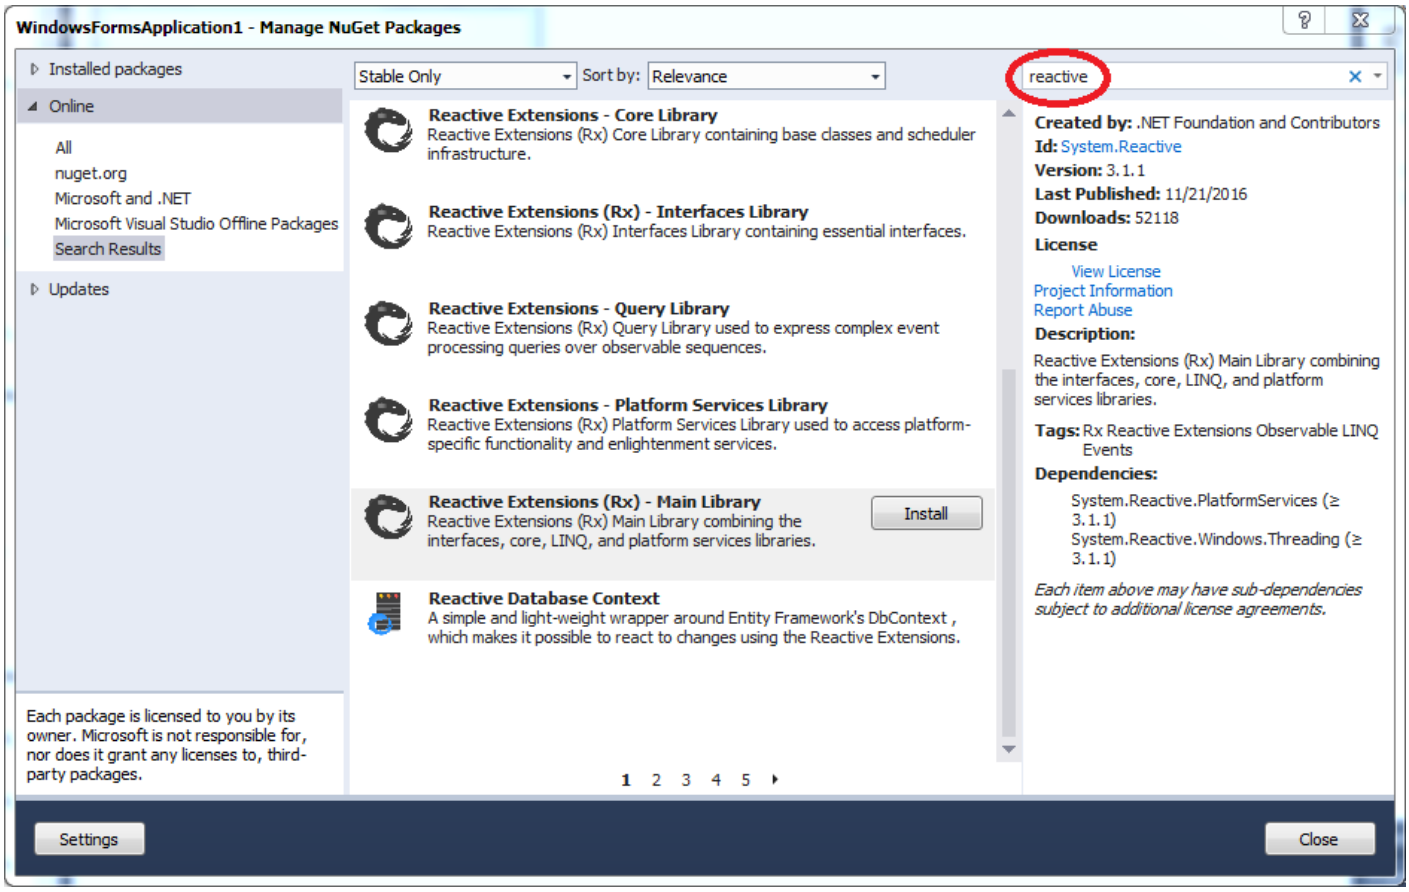
This functionality is not yet available for OPC UA PubSub.

5.4.1 Reactive Programming Model for OPC Data (Classic and UA)

Microsoft Reactive Extensions (Rx) and reactive programming in general is a big subject and cannot be covered in any detail here. We will only describe the specifics that OPC Data Client brings to Rx, by bridging it with the world of OPC.

The power of reactive extensions is in their high level of abstraction, asynchronous nature, and ability of composition.

Microsoft provides Reactive Extensions (Rx) as a NuGet package. Reference the corresponding package in your project, in order to get access to the Rx types. In Visual Studio, use the “Tools -> Library Package Manager” command, and search for “Reactive Extensions – Main Library”, as on the following picture.



5.4.1.1 OPC Reactive Extensions (Rx/OPC)

OPC Reactive Extensions (Rx/OPC) are OPC-specific classes that implement the Rx interfaces. With Rx/OPC, you can e.g.:

- Create observable collections (data streams) that provide OPC data.
- Consume (observe) data streams, and process them using OPC.
- Combine data flows to create more complex operations.

For OPC Data Access, OPC XML-DA and OPC-UA data, Rx/OPC gives you the ability to work with flows representing OPC (monitored) item changes, or flows that represents values to be written into an OPC item (node).

In the example below, your application is required to continuously monitor the value of an OPC item, and when it is available (there is no failure obtaining the value), make some computations with it (we will multiply the value by 1000), and write the results into a different OPC item. This logic can be expressed by following code:

Reactive transfer of OPC DA item values

```
DAItemChangedObservable.Create<int>(
        "", "OPCLabs.KitServer.2", "Simulation.Incrementing (1 s)", 100)
    .Where(e => e.Exception == null)
    .Select(e => e.Vtq.Value * 1000)
    .Subscribe(DAWriteItemValueObserver.Create<int>(
```

```
        "", "OPCLabs.KitServer.2", "Simulation.Register_I4"));
```

Let's dissect what this example does:

1. It creates an observable sequence for significant changes in OPC-DA item "Simulation.Incrementing (1 s)".
2. The "Where" clause filters (from the observable sequence) only the changes that have a null Exception, i.e. those that carry a valid DAVtq object (value/timestamp/quality).
3. The "Select" clause takes the actual value from the Vtq property (it is of type DAVtq<int>), and returns the value multiplied by 1000.
4. An observer that writes incoming vales into the "Simulation.Register_I4" OPC-DA item is created.
5. The observer is subscribed to the transformed (processed) observable sequence.

As you can see, the code that does this kind of OPC data processing is very concise – all the extra "plumbing" needed in imperative programming model is gone, and only the meaningful pieces remain. Programs written in this way clearly express their intent, and the logic that handles certain functionality is concentrated in one place and not spread around various classes and methods.

5.4.1.2 OPC Data Observables

The DAItemChangedObservable<TValue> class is an observable for changes in OPC Data Access item or multiple items of type TValue. The UADataChangeNotificationObservable<TValue> class is an observable for changes in OPC-UA monitored item or multiple items of type TValue. It represents a data stream with information about significant data changes in the subscribed items.

Each significant change is represented by an OnNext message of type EasyDAItemChangedEventArgs<T> (for OPC Classic) or EasyUADataChangeNotificationEventArgs<T> (for OPC-UA). This message is used both for successes, when the Exception property is a null reference and the Vtq property (for OPC Classic) or the AttributeData property (for OPC-UA) contains valid data, and for failures, when the Exception property is non-null and contains the failure information.

The OnCompleted and OnError messages (methods of the IObserver) are never sent (not even in case of error related to the OPC item), thus the data stream is not terminated. If your application requires, you can process the data stream further, and filter it or split it by success/failure as needed.

For OPC Classic, you can create instances of DAItemChangedObservable<TValue> either by using its constructor, or with use of a static DAItemChangedObservable class with several overloads of the Create method. The static DAItemChangedObservable.Create methods use the default underlying EasyDAClient object for OPC reactive extensions. If you need to set some parameters in the client object, you can use the ClientSelector property to specify them.

For OPC-UA, you can create instances of UADataChangeNotificationObservable<TValue> either by using its constructor, or with use of a static UADataChangeNotificationObservable class with several overloads of the Create method. The static UADataChangeNotificationObservable.Create methods use the default underlying EasyUAClient object for OPC reactive extensions. If you need to set some parameters in the client object, you can use the ClientSelector property to specify them.

This approach allows the code be expressed only in terms of pure OPC logic, and be not tied to the actual way it is implemented.

The following code fragment creates the observable using one of the Create methods:

Creating OPC DA observable

```
DAItemChangedObservable<double> ramp =
     DAItemChangedObservable.Create<double>(
         "", "OPCLabs.KitServer.2", "Demo.Ramp", 1000);
```

It is recommended that you create the instances using the DAItemChangedObservable.Create (or UADataChangeNotificationObservable.Create) methods unless you have special needs.

5.4.1.3 OPC Data Observers

The DAWriteItemValueObserver<TValue> is an observer that writes incoming values into an OPC Data Access item. The UAWriteValueObserver<TValue> is an observer that writes incoming values into an OPC-UA node (more precisely, into an attribute of a node).

Each OnNext method call on its IObserver<TValue> interface writes the value in the argument into the OPC item or node attribute associated with the observer. OnCompleted and OnError methods do nothing.

For OPC Classic, you can create instances of DAWriteItemValueObserver<TValue> either by using its constructor, or with use of a static DAWriteItemValueObserver class with several overloads of the Create method. The static DAWriteItemValueObserver.Create methods use the default underlying EasyDAClient object for OPC reactive extensions. If you need to set some parameters in the client object, you can use the ClientSelector property to specify them.

For OPC-UA, you can create instances of UAWriteValueObserver<TValue> either by using its constructor, or with use of a static UAWriteValueObserver class with several overloads of the Create method. The static UAWriteValueObserver.Create methods use the default underlying EasyUAClient object for OPC reactive extensions. If you need to set some parameters in the client object, you can use the ClientSelector property to specify them.

This approach allows the code be expressed only in terms of pure OPC logic, and be not tied to the actual way it is implemented.

The following code fragment creates the observer using one of the Create methods:

Creating OPC DA write observer

```
DAWriteItemValueObserver<int> observer =
     DAWriteItemValueObserver.Create<int>(
         "", "OPCLabs.KitServer.2", "Simulation.Register_I4");
```

It is recommended that you create the instances using the DAWriteItemValueObserver.Create (or UAWriteValueObserver.Create) methods unless you have special needs.

5.4.2 Reactive Programming Model for OPC Alarms and Events

Microsoft Reactive Extensions (Rx) and reactive programming in general is a big subject and cannot be covered in any detail here. We will only describe the specifics that OPC Data Client brings to Rx, by bridging it with the world of OPC.

The power of reactive extensions is in their high level of abstraction, asynchronous nature, and ability of composition.

5.4.2.1 OPC Reactive Extensions (Rx/OPC)

OPC Reactive Extensions (Rx/OPC) are OPC-specific classes that implement the Rx interfaces. With Rx/OPC, you can e.g.:

- Create observable collections (data streams) that provide OPC events.
- Consume (observe) data streams, and process them using OPC.
- Combine data flows to create more complex operations.

For OPC Alarms & Events, Rx/OPC gives you the ability to work with flows representing OPC event notifications, or flows that represent OPC event conditions to be acknowledged.

5.4.2.2 OPC-A&E Observables

The AENotificationObservable class is an observable for notifications about OPC events. It represents a data stream with information about subscribed events.

Each significant change is represented by an OnNext message of type EasyAENotificationEventArgs. This message is used both for successes, when the Exception property is a null reference, and for failures, when the Exception property is non-null and contains the failure information.

The OnCompleted and OnError messages (methods of the IObserver) are never sent (not even in case of error related to the OPC server communication), thus the data stream is not terminated. If your application requires, you can process the data stream further, and filter it or split it by success/failure as needed.

You can create instances of AENotificationObservable either by using its constructor, or with use of several overloads of the static Create method. The static AENotificationObservable.Create methods use the default underlying EasyAEClient object for OPC reactive extensions. If you need to set some parameters in the client object, you can use the ClientSelector property to specify them. This allows the code be expressed only in terms of pure OPC logic, and be not tied to the actual way it is implemented.

It is recommended that you create the instances using the AENotificationObservable.Create methods unless you have special needs.

5.4.2.3 OPC-A&E Observers

The AEAcknowledgeConditionObserver is an observer that acknowledges OPC event conditions according to incoming values.

Each OnNext method call on its IObserver<AEAcknowledgeConditionArguments> interface acknowledges an OPC event

condition according to the arguments passed to it. OnCompleted and OnError methods do nothing.

You can create instances of AEAcknowledgeConditionObserver either by using its constructor, or with use of several overloads of the static Create method. The static AEAcknowledgeConditionObserver.Create methods use the default underlying EasyAEClient object for OPC reactive extensions. If you need to set some parameters in the client object, you can use the ClientSelector property to specify them. This allows the code be expressed only in terms of pure OPC logic, and be not tied to the actual way it is implemented.

It is recommended that you create the instances using the AEAcknowledgeConditionObserver.Create methods unless you have special needs.

6 Features

This section describes some of the larger OPC Data Client features that deserve separate documentation. They are

- **User Interface (Section 6.1)**
- **Connectivity Model (Section 6.2)**
- **Services (Section 6.3)**
- **Specialized Client Objects (Section 6.4)**

6.1 User Interface

The following table shows which functionality is available for different development platforms:

Development Platform:	**COM**	**.NET Framework**	**.NET Standard**	**Excel** (with **Excel Option (Section 12.1)**)
Features				
OPC Common Dialogs	✓	✓	×	× (1)
OPC Controls	×	✓	×	×
Unsolicited User Interaction				
Console	✓	✓	✓	×
Windows Forms	✓	✓	×	✓

Notes: (1) This functionality is not directly available on the development platform, but can be achieved by combining with VBA code (through COM platform).

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

6.1.1 OPC Common Dialogs

OPC Data Client contains a set of Windows Forms dialog boxes for performing common OPC-related tasks such as selecting an OPC server or OPC item in OPC "Classic", or selecting an OPC server endpoint, or an OPC data node within the server, in OPC Unified Archiecture.

The dialog objects are all derived from System.Windows.Forms.CommonDialog, providing consistent and well-known programming interface to use.

You can drag any of the dialog components from the Visual Studio toolbox to the designer surface, and then configure its properties. It is also possible to use the dialog components without the designer support – simply instantiate the dialog

class, and work with its properties and methods from your code.

The properties of each dialog that have significance for its functionality are categorized as follows:

Category	Description
Mode	Determines the overall behavior of the dialog. For example, some dialogs allow you to choose whether a single selection or multi-selection will be performed.
Inputs	Information necessary for running the dialog that the user cannot change. For example, with an OPC-DA Item Dialog, the dialog inputs consists of the machine name and the OPC server to be browsed.
Inputs/Outputs	Information that can be provided as initial data, but the dialog user can change it. For example, with an OPC-DA Item Dialog, the information about the selected item can passed into the dialog so that it is pre-selected at the beginning. Corresponding information may also exist in the Outputs category; the difference is that the Outputs contain more details (typically in the form of some of the XXXXElement classes), while the Inputs/Outputs only contains the necessary identifying data (could be in form of XXXXDescriptor classes).
Outputs	The selection(s) that the user has made in the dialog.

All OPC browsing dialogs have an additional SizeFactor property. The property allows the developer to influence the (initial) size of the dialog on screen. It can be set to one of the pre-defined values (SizeFactors.Small/Normal/Large/ExtraLarge), or to any SizeF structure, defining a width and height relative to the normal size. An additional SizeFactorName is provided primarily to allow easy access to this feature to COM callers.

All OPC browsing dialogs also have an additional RetainAppearance property. When set (which is the default behavior), the dialog retains its appearance (mainly, the location and size), between invocations. It is also possible to call the RevertAppearance() method on the dialog, to restore the original values.

When any of the common dialog components is placed onto the designer surface and its properties configured, it can be tested without a need to build the project. To perform the test, use the “Test Dialog” command, available from the context menu on the dialog component itself, or the same command in the Properties window, when the dialog component is selected (you may have to right-click in the property grid and check "Commands" first, to display the commands under the property grid).

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

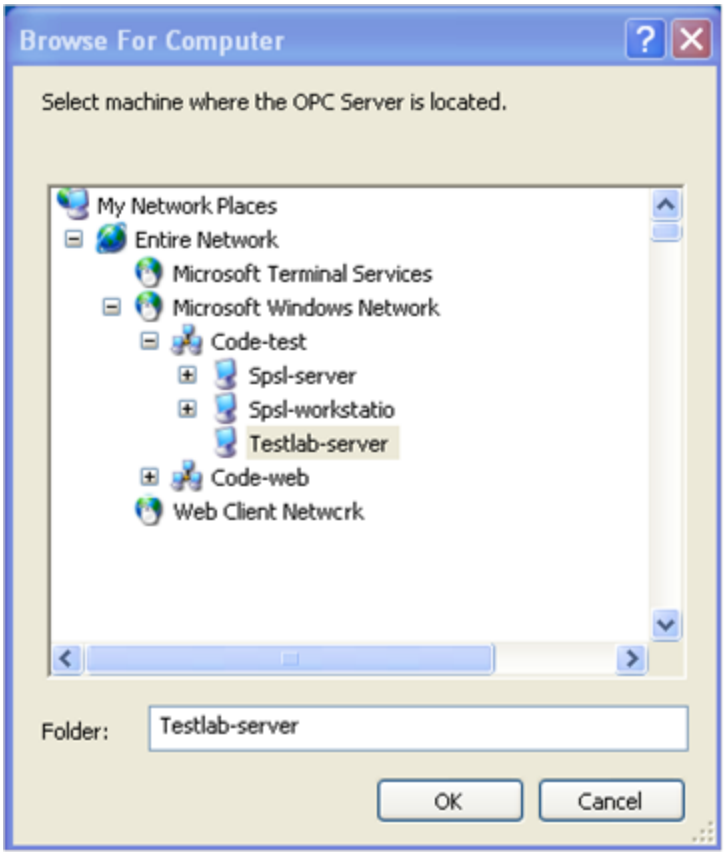
6.1.1.1 OPC-DA Common Dialogs

Articles in this section apply to OPC "Classic" DA and OPC XML-DA.

6.1.1.1.1 Computer Browser Dialog (OPC DA usage)

Icon: 

OPC servers are usually deployed on the network, and accessed via DCOM. In order to let the user select the remote computer where the OPC server resides, you can use the ComputerBrowserDialog object.



Call the ShowDialog method, and if the result is equal to DialogResult.OK, the user has selected the computer, and its name can be retrieved from the SelectedName property.

C++

```
// This example shows how to let the user browse for computers on the network.

#include "stdafx.h"    // Includes "QuickOpc.h", and other commonly used files
#include "ShowDialog.h"

namespace _ComputerBrowserDialog
{
    void ShowDialog::Main()
    {
        // Initialize the COM library
        CoInitializeEx(NULL, COINIT_MULTITHREADED);
        {
            //
            _ComputerBrowserDialogPtr DialogPtr(__uuidof(ComputerBrowserDialog));

            //
            DialogResult dialogResult = DialogPtr->ShowDialog(NULL);
```

```
            // Display results
            _tprintf(_T("%d\n"), dialogResult);
            _tprintf(_T("%s\n"), (LPCTSTR)CW2CT(DialogPtr->SelectedName));
        }
         // Release all interface pointers BEFORE calling CoUninitialize()
        CoUninitialize();
    }
}
```

Free Pascal

```
// This example shows how to let the user browse for computers on the network.

class procedure ShowDialog.Main;

    WScript.Quit
End If

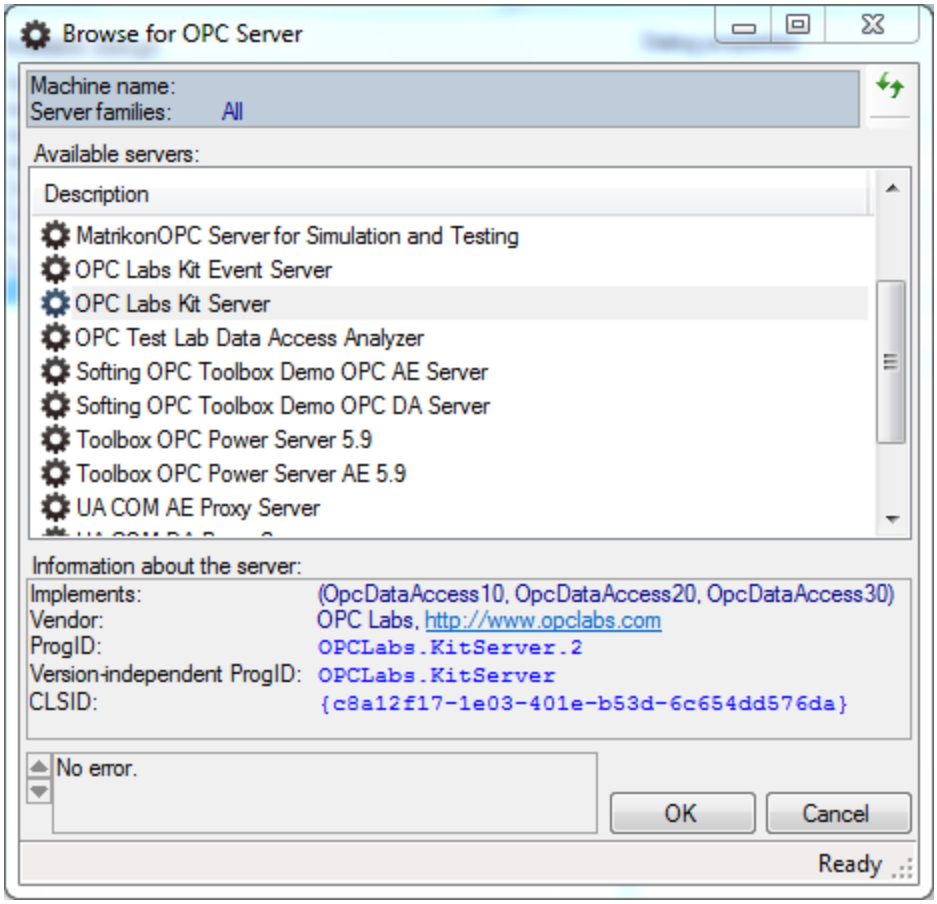
' Display results
WScript.Echo Dialog.SelectedName
```

6.1.1.1.2 OPC Server Dialog (OPC DA usage)

Icon : 

If you do not know upfront which OPC server to connect to, and do not have this information from any other source, your application will need to allow the user select the OPC server(s) to work with. The OPC Server Dialog (OpcServerDialog class) allows the user to select the OPC server interactively from the list of OPC Data Access servers installed on a particular machine.

Here is an example of OPC Server dialog in action:



The ServerFamilies property of the dialog determines whether OPC Data Access servers, OPC Alarms&Events servers, other servers, or a combination of them will be browsed. By default, all server families are browsed. In order to limit the browsing to OPC Data Access servers only, set the ServerFamilies property to OpcDataAccess enumeration member.

To run the dialog, set the Location property to the name of the computer that is to be browsed, and call the ShowDialog method. If the result is equal to DialogResult.OK, the user has selected the OPC Data Access server, and information about it can be retrieved from the ServerElement property.

VBScript

```
Rem This example shows how to let the user browse for an OPC "Classic" server.

Option Explicit

Const DialogResult_OK = 1

Dim ServerDialog: Set ServerDialog =
CreateObject("OpcLabs.EasyOpc.Forms.Browsing.OpcServerDialog")
'ServerDialog.Location = ""
Dim dialogResult: dialogResult = ServerDialog.ShowDialog
WScript.Echo dialogResult

If dialogResult <> DialogResult_OK Then
    WScript.Quit
```

```
End If

' Display results
WScript.Echo ServerDialog.ServerElement
```

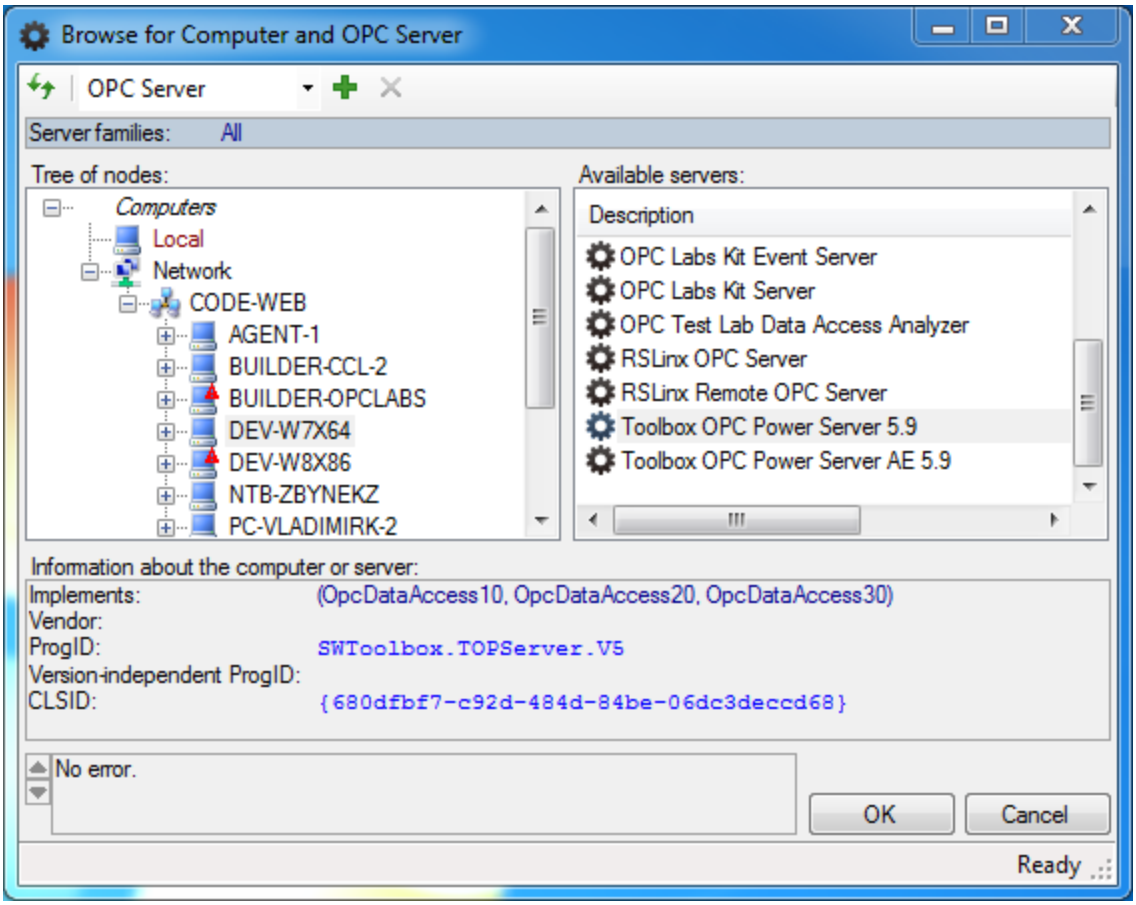
6.1.1.1.3 OPC Computer and Server Dialog

Icon: 

With OpcComputerAndServerDialog, your application can integrate a dialog box from which the user can select a computer and an OPC server residing on it. This dialog box combines functions of the Computer Browser Dialog -  and OPC Server Dialog into a single dialog.

In addition, the user can add Computer nodes in case the particular computer is not visible on the network, or add OPC Server nodes in case the OPC Server is known to exist but is not returned by OPC Server enumeration feature.

Here is an example of OPC Computer and Server dialog in action:

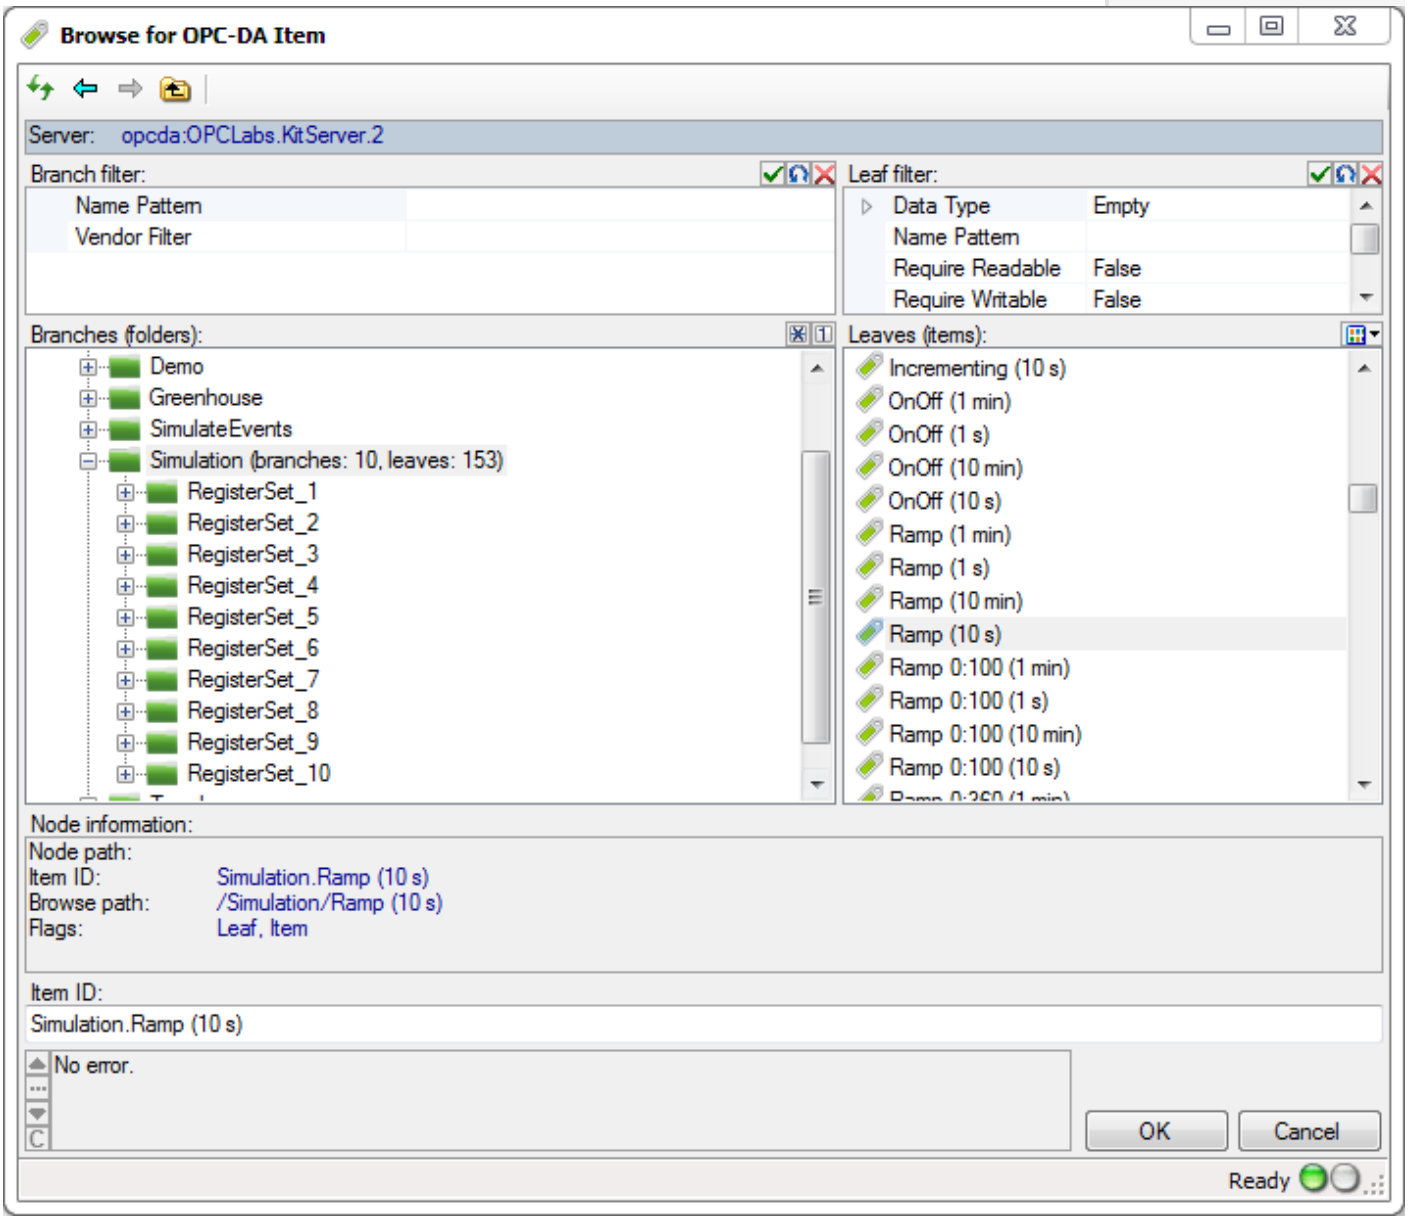


6.1.1.1.4 OPC-DA Item Dialog

Icon: 

The OPC-DA Item Dialog (DAItemDialog class) allows the user to interactively select the OPC item residing in a specific OPC server.

In This Topic



Use the ServerDescriptor property to specify the OPC Data Access server whose items are to be browsed, and call the ShowDialog method. If the result is equal to DialogResult.OK, the user has selected the OPC item, and information about it can be retrieved from the NodeElement property.

Object Pascal

```
// This example shows how to let the user browse for an OPC Data Access item.

class procedure ShowDialog.Main;
```

```
var
  ItemDialog: OpcLabs_EasyOpcForms_TLB._DAItemDialog;
begin
  // Instantiate the dialog object
  ItemDialog := CoDAItemDialog.Create;

  ItemDialog.ServerDescriptor.ServerClass := 'OPCLabs.KitServer.2';

  ItemDialog.ShowDialog(nil);

  // Display results
  WriteLn(ItemDialog.NodeElement.ToString);
end;
```

VBScript

```
Rem This example shows how to let the user browse for an OPC Data Access item.

Option Explicit

Const DialogResult_OK = 1

Dim ItemDialog: Set ItemDialog =
CreateObject("OpcLabs.EasyOpc.DataAccess.Forms.Browsing.DAItemDialog")
ItemDialog.ServerDescriptor.ServerClass = "OPCLabs.KitServer.2"
Dim dialogResult: dialogResult = ItemDialog.ShowDialog
WScript.Echo dialogResult

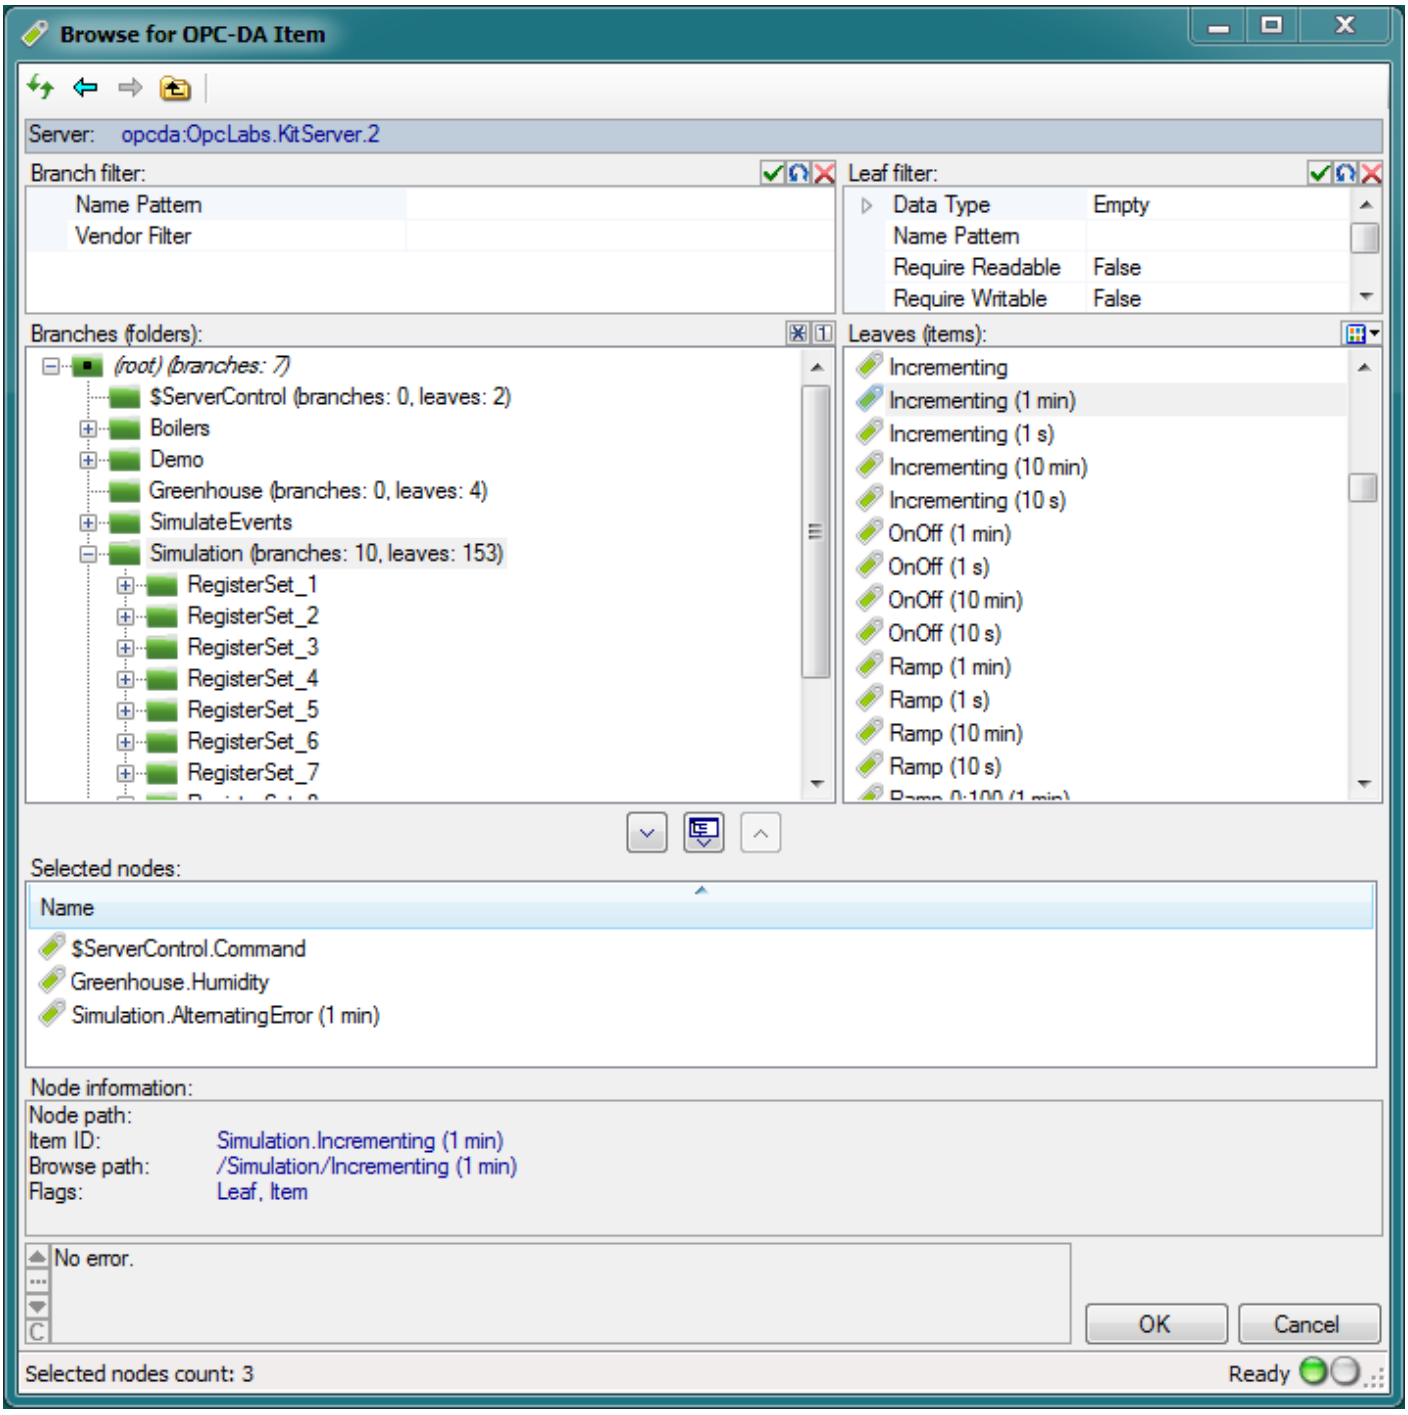
If dialogResult <> DialogResult_OK Then
    WScript.Quit
End If

' Display results
WScript.Echo "NodeElement: " & ItemDialog.NodeElement
```

The DAItemDialog component retains the filter setting for each node between the invocations of the dialog, making it faster for the user to navigate during the subsequent invocations.

Multi-selection

When you set the MultiSelect property of the DAItemDialog to true, the dialog will allow the user to select any number of OPC-DA items. In the multi-select mode, the dialog looks similar to this:



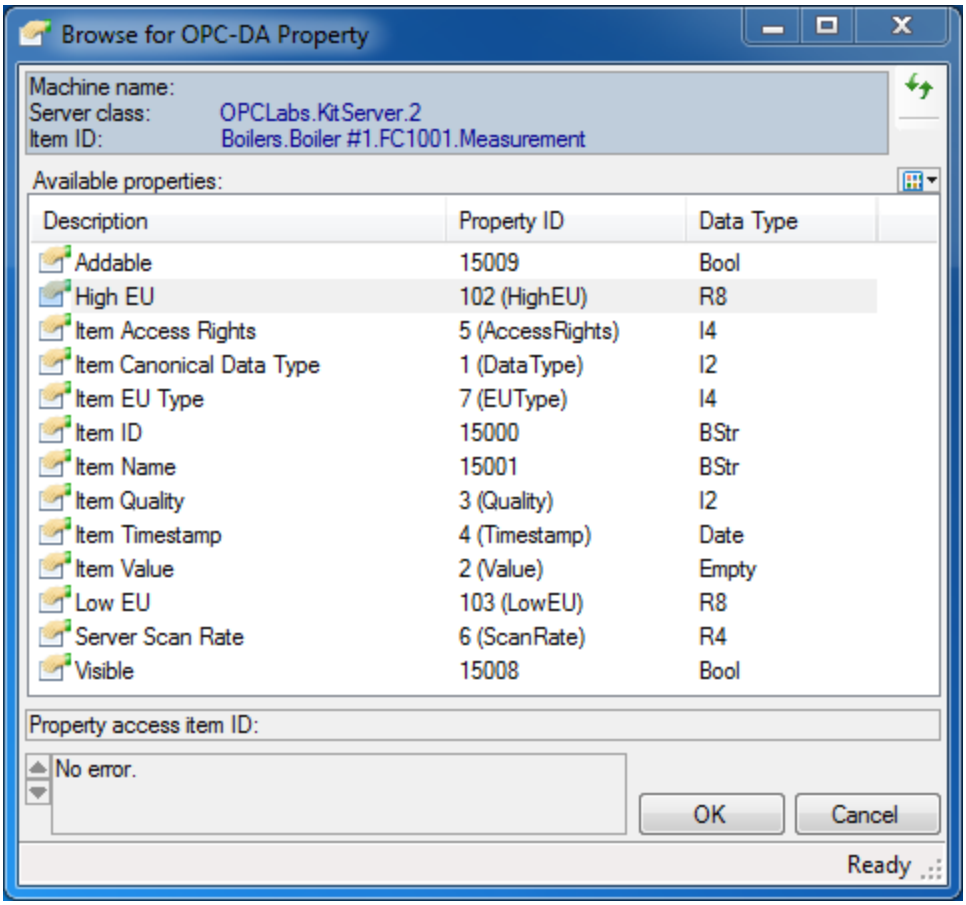
The list below the branches and leaves (labeled “Selected nodes”) contains the set of nodes that the user has selected in the dialog. The user can freely add nodes to this list, or remove them. The selected set is carried over to next invocation of the dialog, unless you change it from the code.

In the multi-selection mode, the set of nodes selected on input (if any) is in the NodeDescriptors property. On the output, the dialog fills the information about selected nodes into the NodeElements property (and updated the NodeDescriptors property as well).

6.1.1.1.5 OPC-DA Property Dialog

Icon: 

The OPC-DA Property Dialog (DAPropertyDialog class) allows the user to interactively select the OPC property on a specific OPC item.



Use the ServerDescriptor property to specify the OPC Data Access server whose items are to be browsed, set the NodeDescriptor property to the OPC Item Id needed, and then call the ShowDialog method. If the result is equal to DialogResult.OK, the user has selected the OPC property, and information about it can be retrieved from the PropertyElement property.

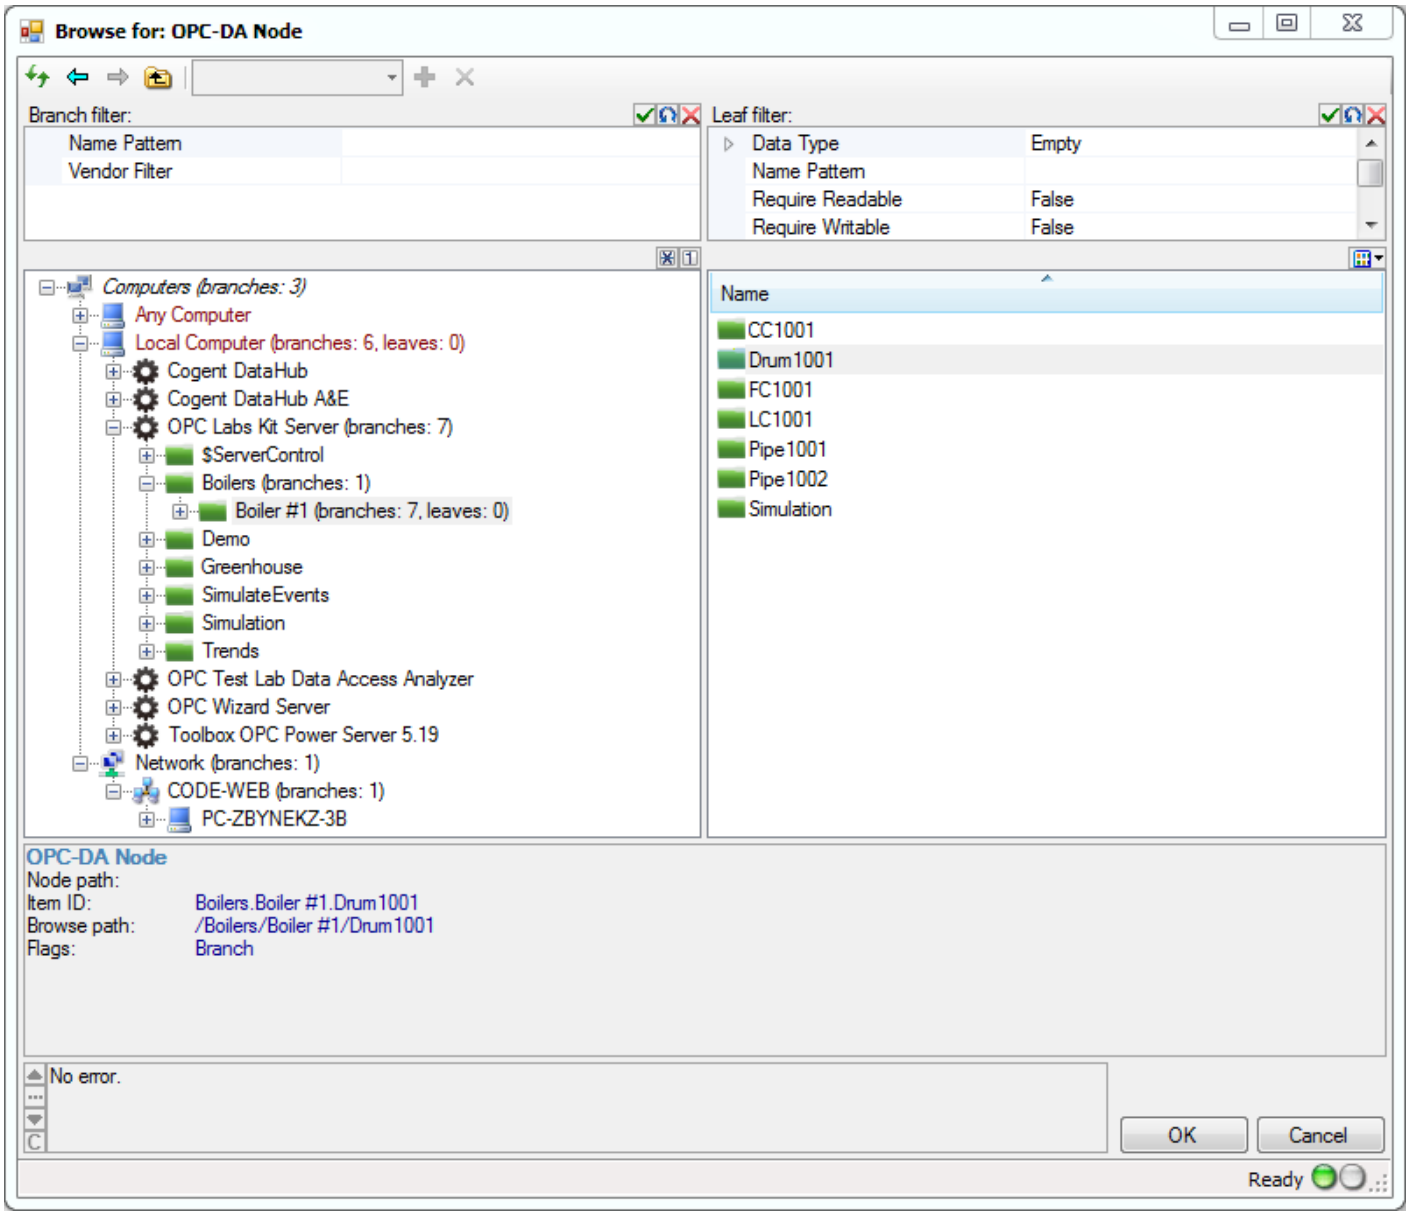
6.1.1.1.6 Generic OPC Browsing Dialog (OPC DA usage)

Icon: 

With OpcBrowseDialog, your application can integrate a dialog with various OPC nodes from which the user can select. This dialog can be configured to serve many different purposes.

Here is an example of the generic OPC browsing dialog in action:

In This Topic

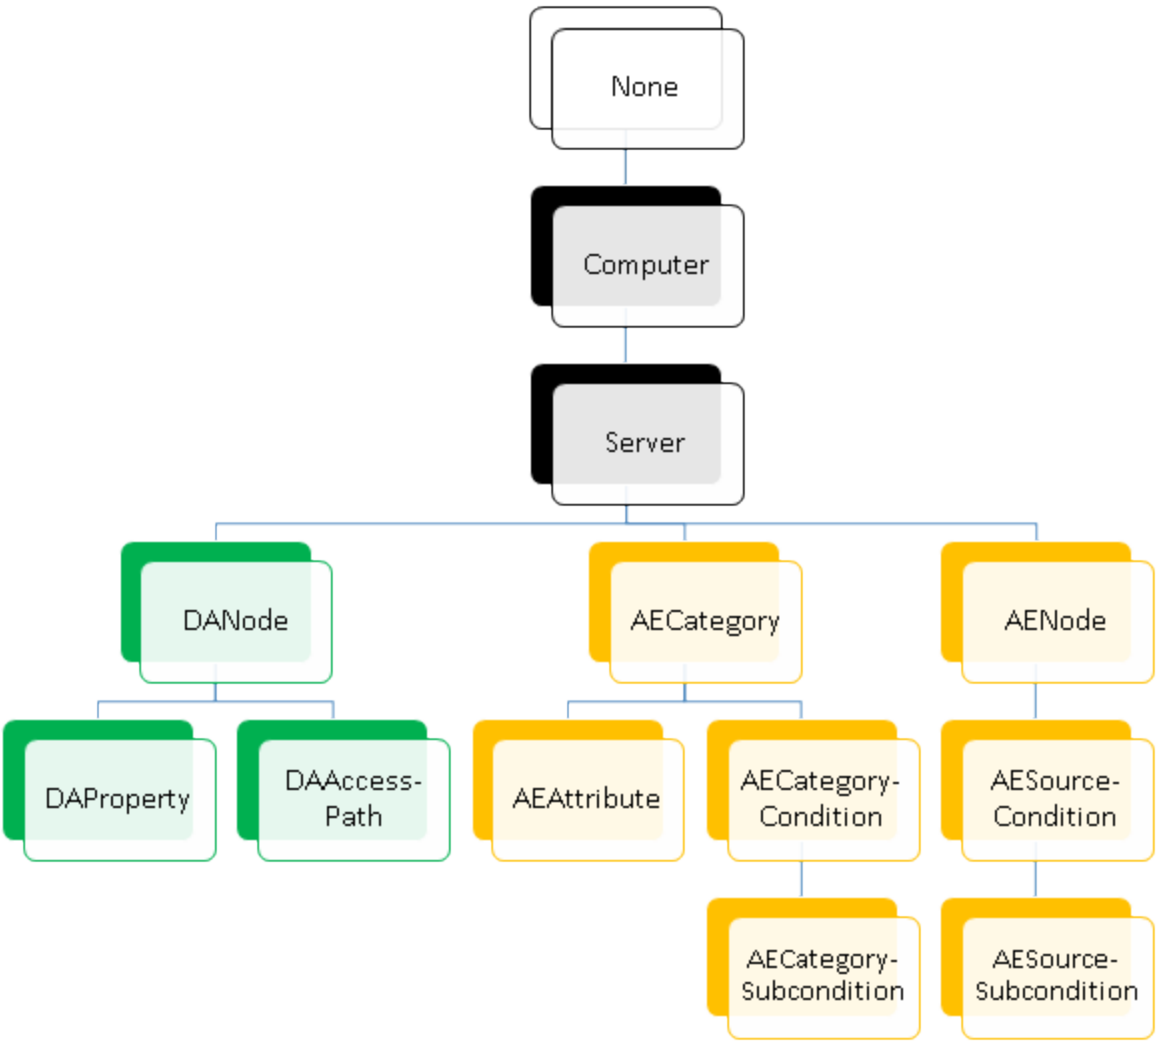


The way the dialog operates is controlled by two main properties:

- Mode.AnchorElementType determines the part of the selection that is given on input and cannot be changed by the user.
- Mode.SelectElementType determines the type of the element that the user needs to select in order to finalize the dialog.

Values of these properties can be selected from the OpcElementType enumeration, which has members for various types of elements that you encounter when working with OPC.

The following chart shows a hierarchy of element types that you can choose from:



For example, let' say that you set Mode.AnchorElementType to Server, and Mode.SelectElementType to DAProperty. This will cause the dialog to allow the user to browse for an OPC Item (node) on the server you specify, and then for an OPC property on that item.

In this case, before you run the dialog, you need to provide it with values for the InputOutputs.CurrentNodeDescriptor.ServerDescriptor.Location and InputOutputs.CurrentNodeDescriptor.ServerDescriptor.ServerClass properties, because those define your "anchor" element (Server) that the user cannot change. The dialog will only allow the user to finalize it (besides cancelling) after an OPC property is fully selected, because that is your Mode.SelectElementType. After the dialog is successfully finalized, the information about the user's choice will be available in the Outputs.CurrentNodeElement.DANodeElement and Outputs.CurrentNodeElement.DAPropertyElement properties.

Note that in addition to the "minimal" scenario described above, you can also pre-set the initial node or property, using the InputOutputs.CurrentNodeDescriptor.DANodeDescriptor or InputOutputs.CurrentNodeDescriptor.DAPropertyDescriptor.PropertyId properties, and after the selection is made, these properties will be updated to the new selection as well. This way, if you run the dialog again with the same value, the initial selection will be where the user has left it the last time the dialog was run.

Obviously, the chosen Mode.SelectElementType must be a child or indirect ancestor of chosen Mode.AnchorElementType in the hierarchy. For example, it would be an error to set Mode.AnchorElementType to AECategory and Mode.SelectElementType to DAProperty.

Object Pascal

```
// This example shows how to let the user browse for an OPC Data Access node.

class procedure ShowDialog.Main;
var
  BrowseDialog: OpcLabs_EasyOpcForms_TLB._OpcBrowseDialog;
begin
  // Instantiate the dialog object
  BrowseDialog := CoOpcBrowseDialog.Create;

  BrowseDialog.ShowDialog(nil);

  // Display results
  WriteLn(BrowseDialog.Outputs.CurrentNodeElement.DANodeElement.ToString);
end;
```

VBScript

```
Rem This example shows how to let the user browse for an OPC Data Access node.

Option Explicit

Const DialogResult_OK = 1

Dim BrowseDialog: Set BrowseDialog =
CreateObject("OpcLabs.EasyOpc.Forms.Browsing.OpcBrowseDialog")
Dim dialogResult: dialogResult = BrowseDialog.ShowDialog
WScript.Echo dialogResult

If dialogResult <> DialogResult_OK Then
    WScript.Quit
End If

' Display results
WScript.Echo BrowseDialog.Outputs.CurrentNodeElement.DANodeElement
```

Multi-selection

It is also possible to configure the dialog for a multi-selection. In this mode, the user can select zero, one, or more nodes. In order to enable the multi-select mode, set the Mode.MultiSelect property to true. In the multi-select mode, the initial

set of the selected nodes (when the dialog is first displayed to the user) is given by the contents of the InputOutputs.SelectionDescriptors collection. When the user makes the selection and accepts it by closing the dialog, this collection is updated, and also, all information about the selected nodes is placed to the Outputs.SelectionElements collection.

Other settings

There are also ways to control some finer aspects of the dialog. For example, the Mode.ShowListBranches property (defaults to true) controls whether the branches of the tree are also displayed in the list view.

6.1.1.2 OPC-A&E Common Dialogs

6.1.1.2.1 Computer Browser Dialog (OPC A&E)

Icon: 

With ComputerBrowserDialog object, you can present your user with a dialog for selecting the remote computer where the OPC server resides.

For more information, see the Computer Browser dialog under “User Interface for OPC-DA”.

6.1.1.2.2 OPC Server Dialog (OPC A&E usage)

Icon: 

The OPC Server Dialog (OpcServerDialog class) allows the user to select the OPC server interactively from the list of OPC “Classic” servers installed on a particular machine.

To select from OPC Alarms&Events servers, you use the same dialog as with OPC Data Access servers – for details on that dialog, see OPC Server Dialog under “User Interface for OPC-DA”. The only difference is that before running the dialog, you need to make sure that its ServerFamilies property is set so that it includes (or only contains) the OpcAlarmsAndEvents enumeration member.

6.1.1.2.3 OPC Computer and Server Dialog

Icon: 

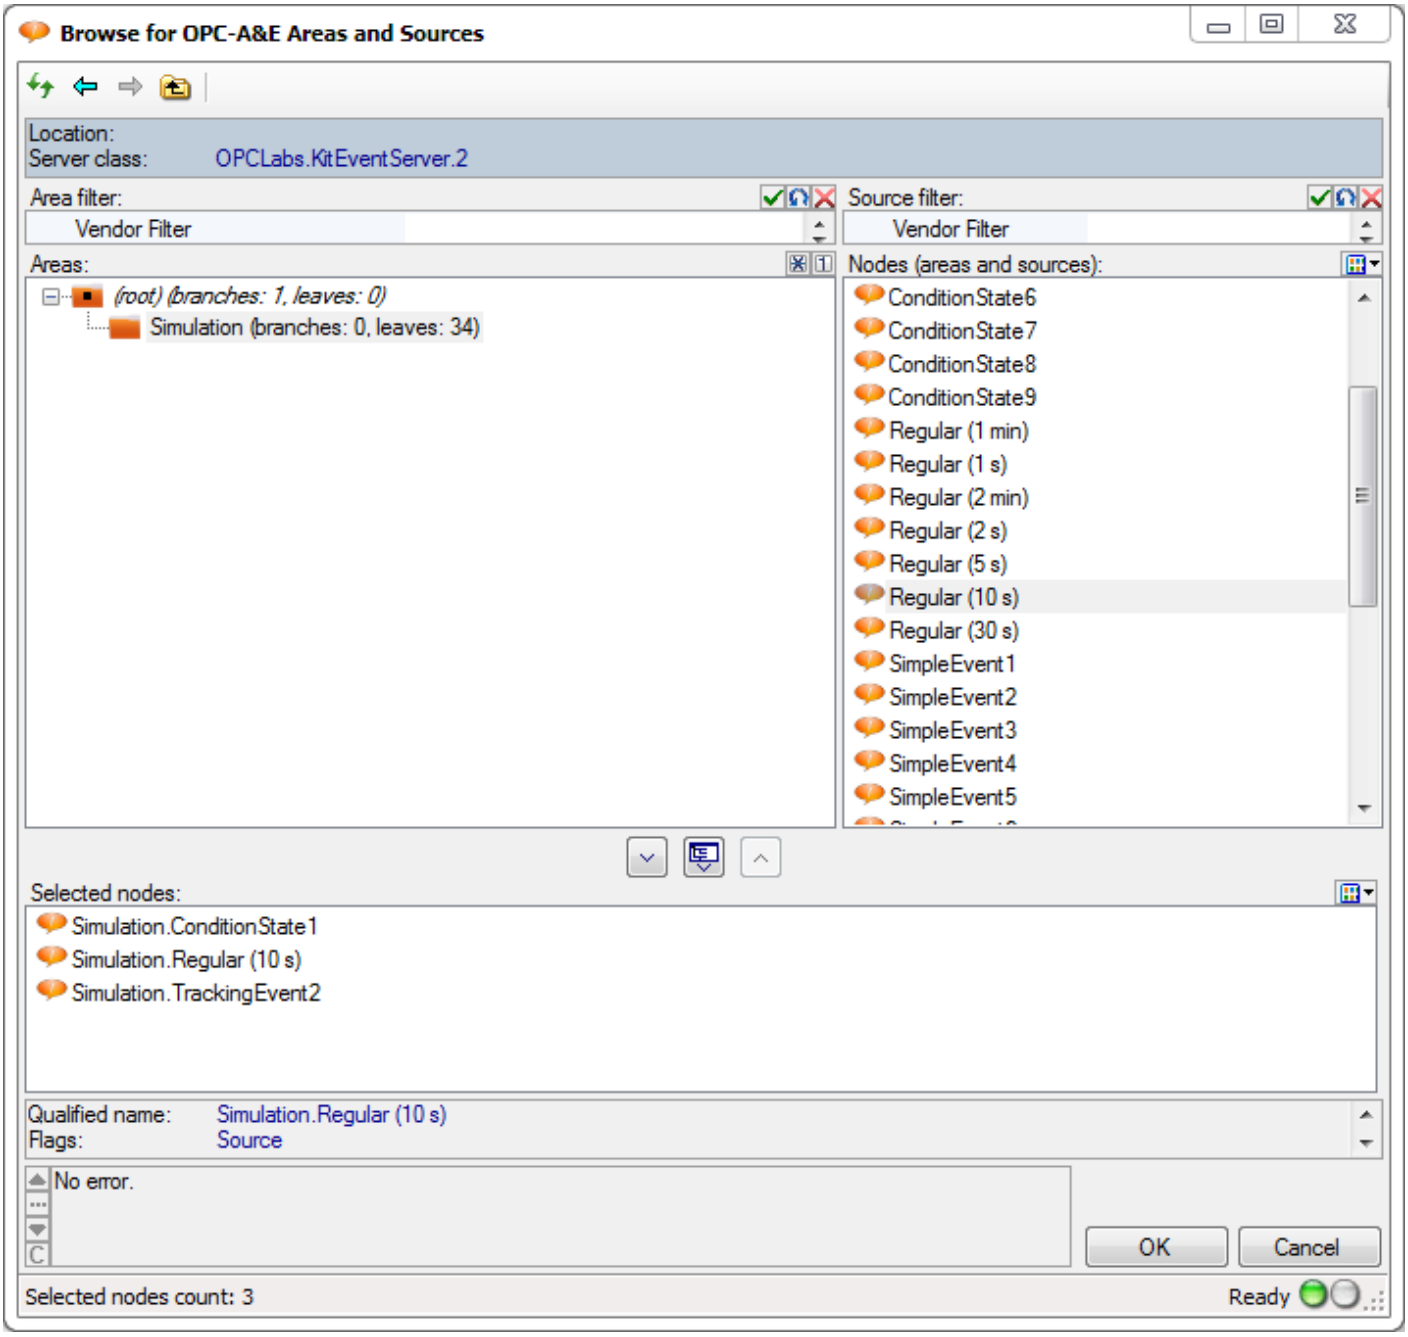
With OpcComputerAndServerDialog, your application can integrate a dialog box from which the user can select a computer and an OPC server residing on it.

This dialog is identical to OPC Computer and Server Dialog described in the OPC-DA Common Dialogs chapter. The only difference is that before running the dialog, you need to make sure that its ServerFamilies property is set so that it includes (or only contains) the OpcAlarmsAndEvents enumeration member.

6.1.1.2.4 OPC-A&E Area or Source Dialog

Icon: 

With AEAreaOrSourceDialog, your applicate can integrate a dialog box from which the user can select OPC-A&E event areas or sources:



The MultiSelect property determines whether the dialog allows the user to select multiple nodes as output.

Use the ServerDescriptor property to specify the OPC Alarms&Events server whose items are to be browsed, and call the ShowDialog method. If the result is equal to DialogResult.OK, the user has finished the selection, and information about it can be retrieved.

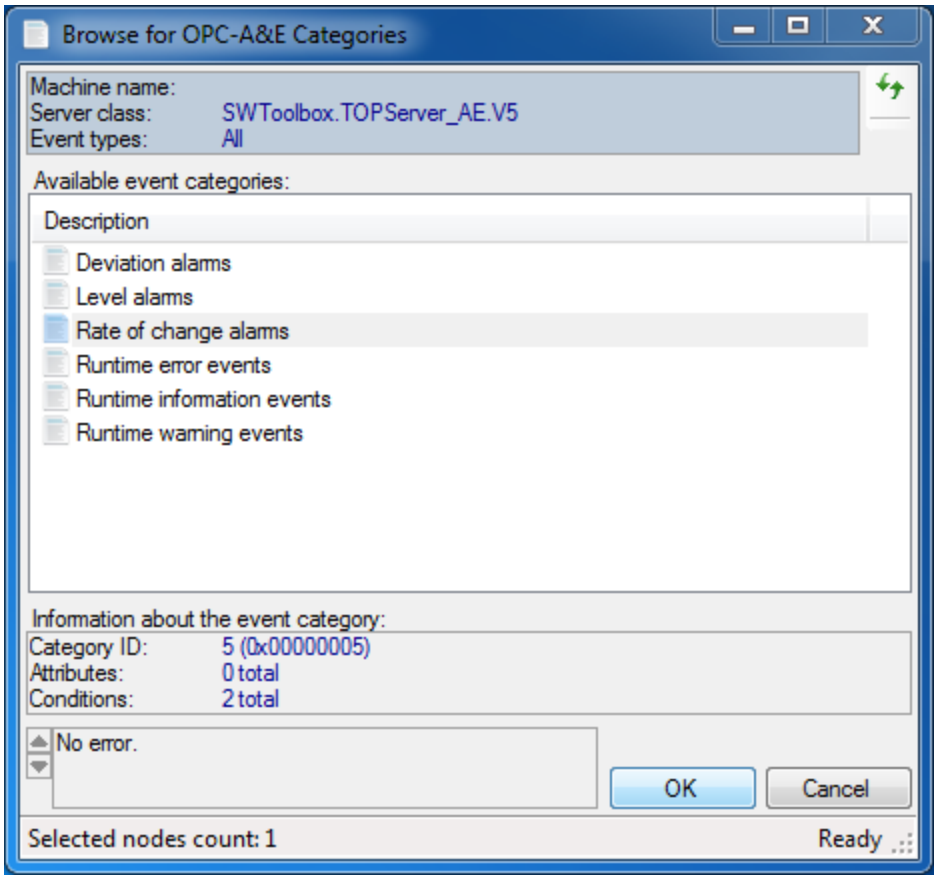
When the dialog is in single-select mode, you can obtain the information about the selected event area or source from the NodeDescriptor property. When the dialog is in multi-select mode, the information about the selected event areas is in the AreaElements property, and the information about the selected event sources in the SourceElements property; all

event areas and nodes are available together in the NodeElements property.

6.1.1.2.5 OPC-A&E Category Dialog

Icon: 

With AECategoryDialog, your application can integrate a dialog box from which the user can select from OPC-A&E event categories provided by the OPC server:



The MultiSelect property determines whether the dialog allows the user to select multiple categories as output.
The EventTypes property determines which event type(s) will be offered for selection.

Use the ServerDescriptor property to specify the OPC Alarms&Events server whose categories are to be browsed, and call the ShowDialog method. If the result is equal to DialogResult.OK, the user has finished the selection, and information about it can be retrieved.

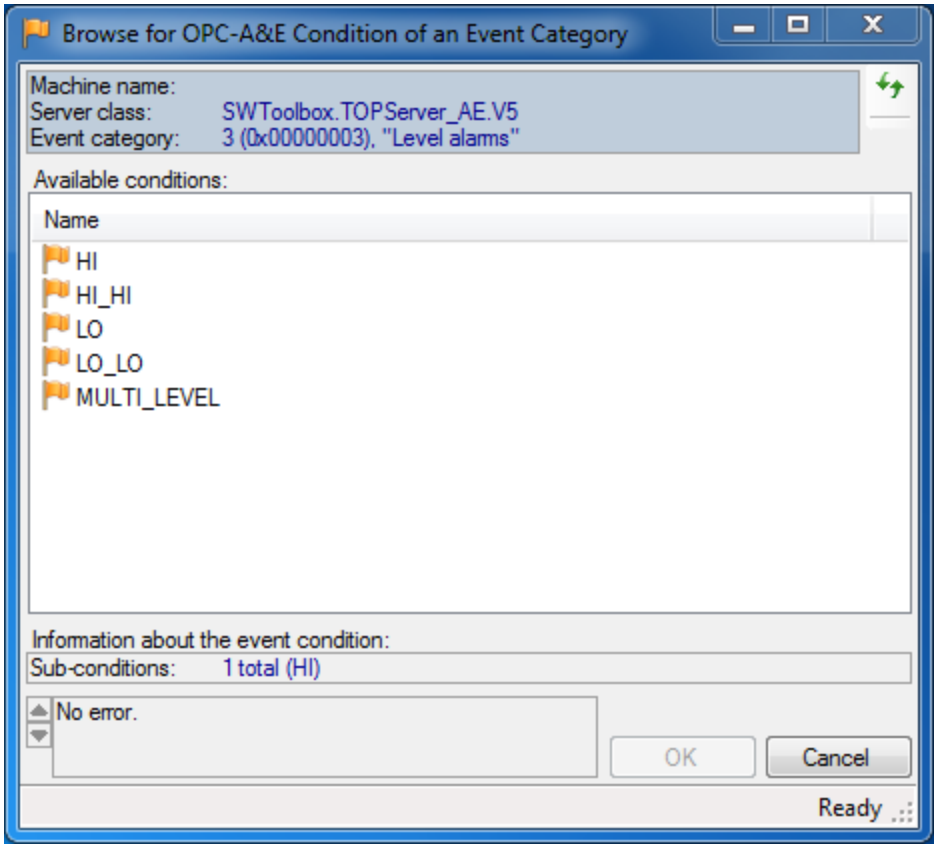
When the dialog is in single-select mode, you can obtain the information about the selected category from the CategoryElement or CategoryId property. When the dialog is in multi-select mode, the information about the selected categories is in the CategoryElements and CategoryIds properties.

6.1.1.2.6 OPC-A&E Category Condition Dialog

Icon: 

With AECategoryConditionDialog, your application can integrate a dialog box from which the user can select OPC-A&E

category available on a specified event condition:

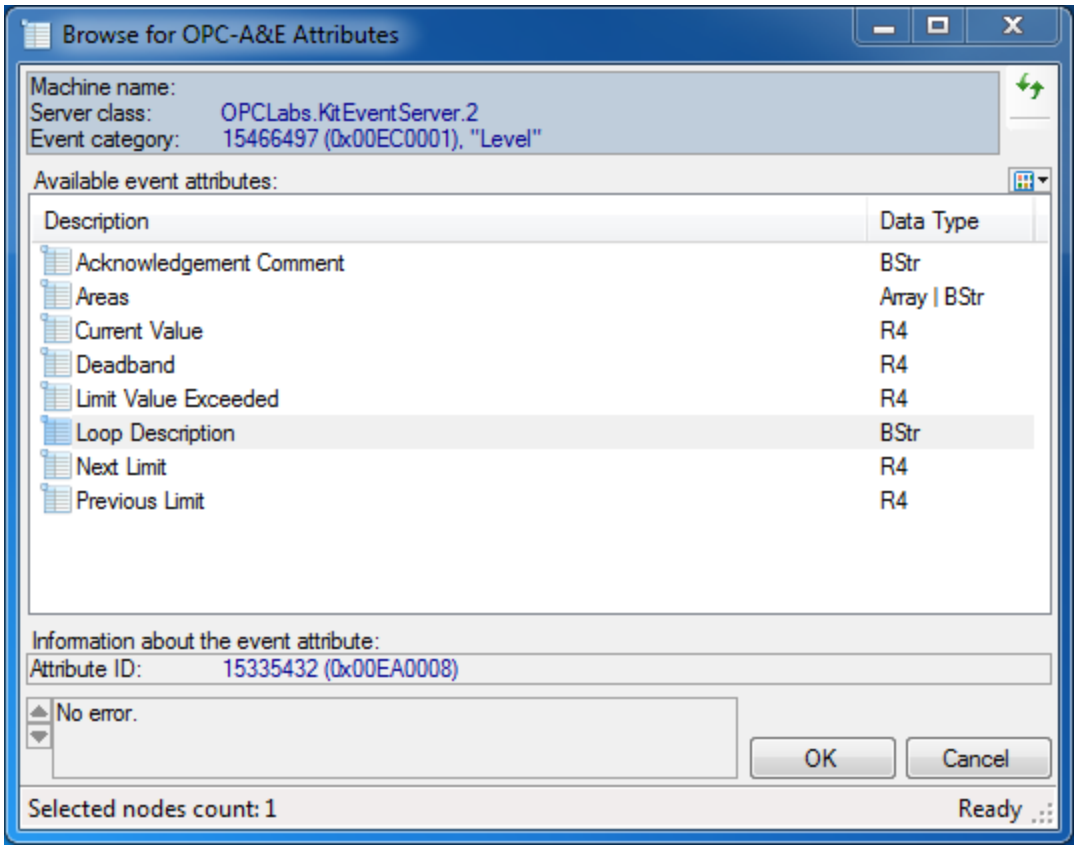


Use the ServerDescriptor property to specify the OPC Alarms&Events server, and the CategoryId property to specify the event category to be browsed. Then, call the ShowDialog method. If the result is equal to DialogResult.OK, the user has selected the event condition, and information about it can be retrieved from the ConditionElement or ConditionName property.

6.1.1.2.7 OPC-A&E Attribute Dialog

Icon: 

With AEAttributeDialog, your application can integrate a dialog box from which the user can select OPC-A&E event attributes:



The MultiSelect property determines whether the dialog allows the user to select multiple attributes as output.

Use the ServerDescriptor property to specify the OPC Alarms&Events server and the CategoryId property to specify the event category to be browsed. Then, call the ShowDialog method. If the result is equal to DialogResult.OK, the user has finished the selection, and information about it can be retrieved.

When the dialog is in single-select mode, you can obtain the information about the selected attribute from the AttributeElement or AttributeId property. When the dialog is in multi-select mode, the information about the selected categories is in the AttributeElements and AttributeIds properties.

6.1.1.2.8 Generic OPC Browsing Dialog (OPC A&E usage)

Icon: 

With OpcBrowseDialog, your application can integrate a dialog with various OPC nodes from which the user can select. This dialog can be configured to serve many different purposes.

As this dialog is shared with other OPC specifications, please refer to Generic OPC Browsing Dialog above for more information.

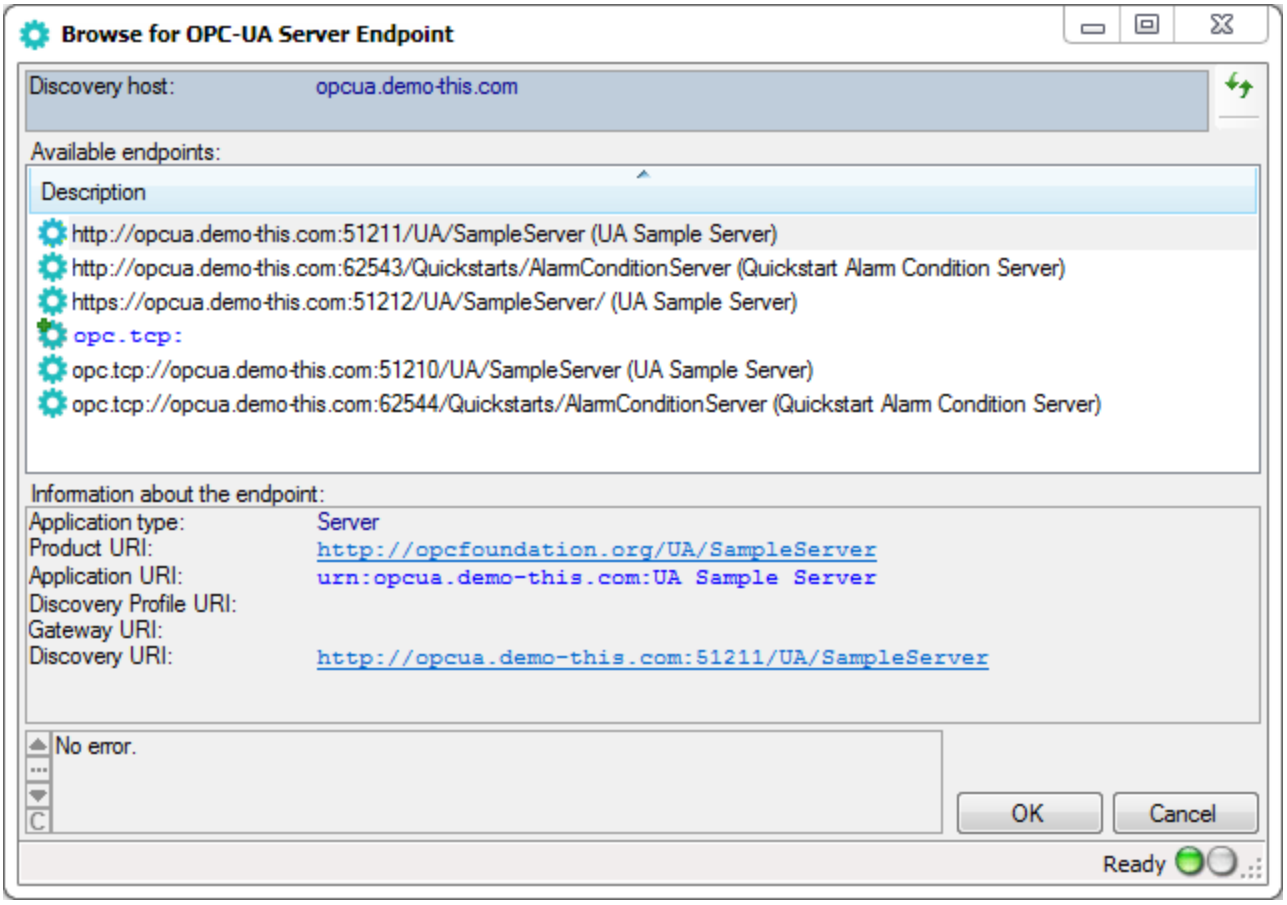
6.1.1.3 OPC-UA Common Dialogs

6.1.1.3.1 OPC-UA Endpoint Dialog

Icon: 

If you do not know upfront which OPC-UA server and its endpoint to connect to, and do not have this information from any other source, your application will need to allow the user select the OPC server(s) to work with. The OPC-UA Endpoint Dialog (UAEndpointDialog class) allows the user to select the OPC server and its endpoint interactively from the list of OPC Unified Architecture servers provided by a LDS (Local Discovery Server) installed on a machine.

Here is an example of OPC-UA Endpoint dialog in action:



To run the dialog, call the ShowDialog method. If the result is equal to DialogResult.OK, the user has selected the OPC UA server, and information about it can be retrieved from the DiscoveryElement property.

Currently, the dialog shows endpoint provided by a LDS (Local Discovery Server) that you set by a static property on the EasyUAClient object. This approach may change in future.

C++

```
// This example shows how to let the user browse for an OPC-UA server endpoint.

#include "stdafx.h"    // Includes "QuickOpc.h", and other commonly used files
#include "ShowDialog.h"

namespace _UAEndpointDialog
{
    void ShowDialog1::Main()
    {
        // Initialize the COM library
```

```
        CoInitializeEx(NULL, COINIT_MULTITHREADED);
        {
            //
            _UAEndpointDialogPtr EndpointDialogPtr(__uuidof(UAEndpointDialog));

            //
            EndpointDialogPtr->DiscoveryHost = L"opcua.demo-this.com";

            //
            DialogResult dialogResult = EndpointDialogPtr->ShowDialog(NULL);

            // Display results
            _tprintf(_T("%d\n"), dialogResult);
            _tprintf(_T("%s\n"), (LPCTSTR)CW2CT(EndpointDialogPtr->DiscoveryElement-
>ToString));
        }
         // Release all interface pointers BEFORE calling CoUninitialize()
        CoUninitialize();
    }
}
```

Free Pascal

```
// This example shows how to let the user browse for an OPC-UA server endpoint.

class procedure ShowDialog.Main;
var
  EndpointDialog: UAEndpointDialog;
begin
  // Instantiate the dialog object
  EndpointDialog := CoUAEndpointDialog.Create;

  EndpointDialog.DiscoveryHost := 'opcua.demo-this.com';

  EndpointDialog.ShowDialog(nil);

  // Display results
  WriteLn(EndpointDialog.DiscoveryElement.ToString);
end;
```

Object Pascal

```
// This example shows how to let the user browse for an OPC-UA server endpoint.

class procedure ShowDialog.Main;
var
  EndpointDialog: OpcLabs_EasyOpcForms_TLB._UAEndpointDialog;
begin
  // Instantiate the dialog object
  EndpointDialog := CoUAEndpointDialog.Create;

  EndpointDialog.DiscoveryHost := 'opcua.demo-this.com';

  EndpointDialog.ShowDialog(nil);

  // Display results
  WriteLn(EndpointDialog.DiscoveryElement.ToString);
```

```
end;
```

Visual Basic (VB 6.)

```
Rem This example shows how to let the user browse for an OPC-UA server endpoint.

Private Sub ShowDialog_Main_Command_Click()
    OutputText = ""

    Dim EndpointDialog As New UAEndpointDialog
    EndpointDialog.DiscoveryHost = "opcua.demo-this.com"

    Dim DialogResult
    DialogResult = EndpointDialog.ShowDialog

    ' Display results
    OutputText = OutputText & DialogResult & vbCrLf
    OutputText = OutputText & EndpointDialog.DiscoveryElement & vbCrLf
End Sub
```

VBScript

```
Rem This example shows how to let the user browse for an OPC-UA server endpoint.

Option Explicit

Const DialogResult_OK = 1

Dim EndpointDialog: Set EndpointDialog =

    WScript.Quit
End If

' Display results
WScript.Echo EndpointDialog.DiscoveryElement
```

6.1.1.3.2 OPC-UA Host and Endpoint Dialog

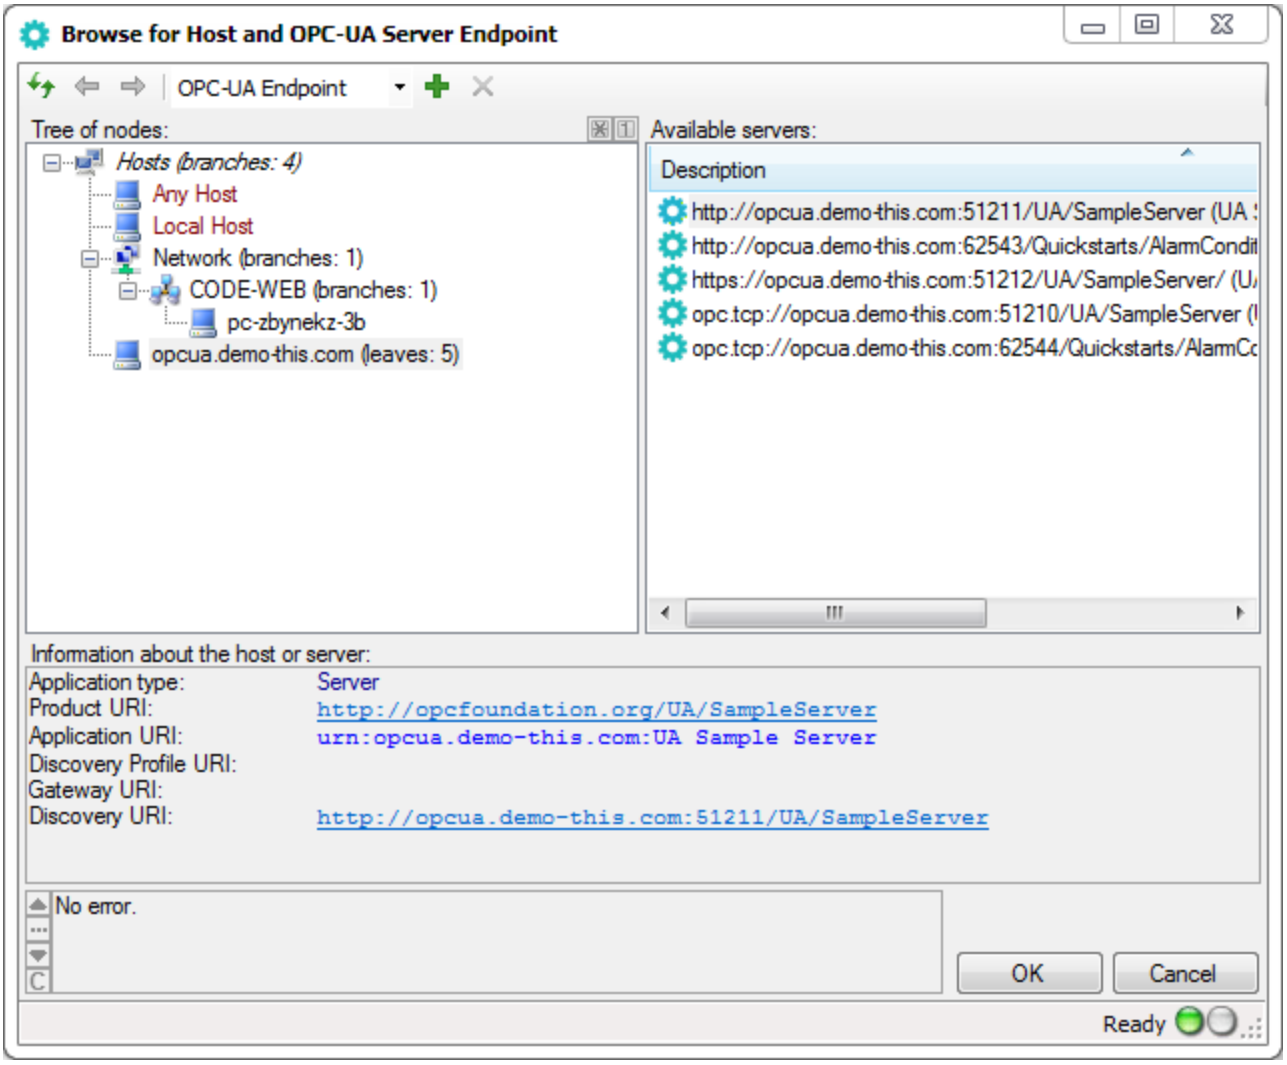
Icon: 

With UAHostAndEndpointDialog, your application can integrate a dialog box from which the user can select a host (computer) and an endpoint of OPC-UA server residing on it. This dialog box combines functions of the Computer Browser Dialog and OPC-UA Endpoint Dialog -  into a single dialog.

In addition, the user can add Host nodes in case the particular computer is not visible on the network, or add OPC-UA

Endpoint nodes in case the OPC_UA Server is known to exist but is not returned by OPC-UA discovery feature.

Here is an example of OPC-UA Host and Endpoint dialog in action:



C++

```
// This example shows how to let the user browse for a host (computer) and an endpoint
of an OPC-UA server residing on it.

#include "stdafx.h"    // Includes "QuickOpc.h", and other commonly used files
#include "ShowDialog.h"

namespace _UAHostAndEndpointDialog
{
    void ShowDialog::Main()
    {
        // Initialize the COM library
        CoInitializeEx(NULL, COINIT_MULTITHREADED);
        {
            //
            _UAHostAndEndpointDialogPtr
```

```
HostAndEndpointDialogPtr(__uuidof(UAHostAndEndpointDialog));

            //
            HostAndEndpointDialogPtr->EndpointDescriptor->Host = L"opcua.demo-
this.com";

            //
            DialogResult dialogResult = HostAndEndpointDialogPtr->ShowDialog(NULL);

            // Display results
            _tprintf(_T("%d\n"), dialogResult);
            _tprintf(_T("HostElement: %s\n"), (LPCTSTR)CW2CT(HostAndEndpointDialogPtr-
>HostElement->ToString));
            _tprintf(_T("DiscoveryElement: %s\n"),
(LPCTSTR)CW2CT(HostAndEndpointDialogPtr->DiscoveryElement->ToString));
        }
         // Release all interface pointers BEFORE calling CoUninitialize()
        CoUninitialize();
    }
}
```

Free Pascal

```
// This example shows how to let the user browse for a host (computer) and

WScript.Echo "DiscoveryElement: " & HostAndEndpointDialog.DiscoveryElement
```

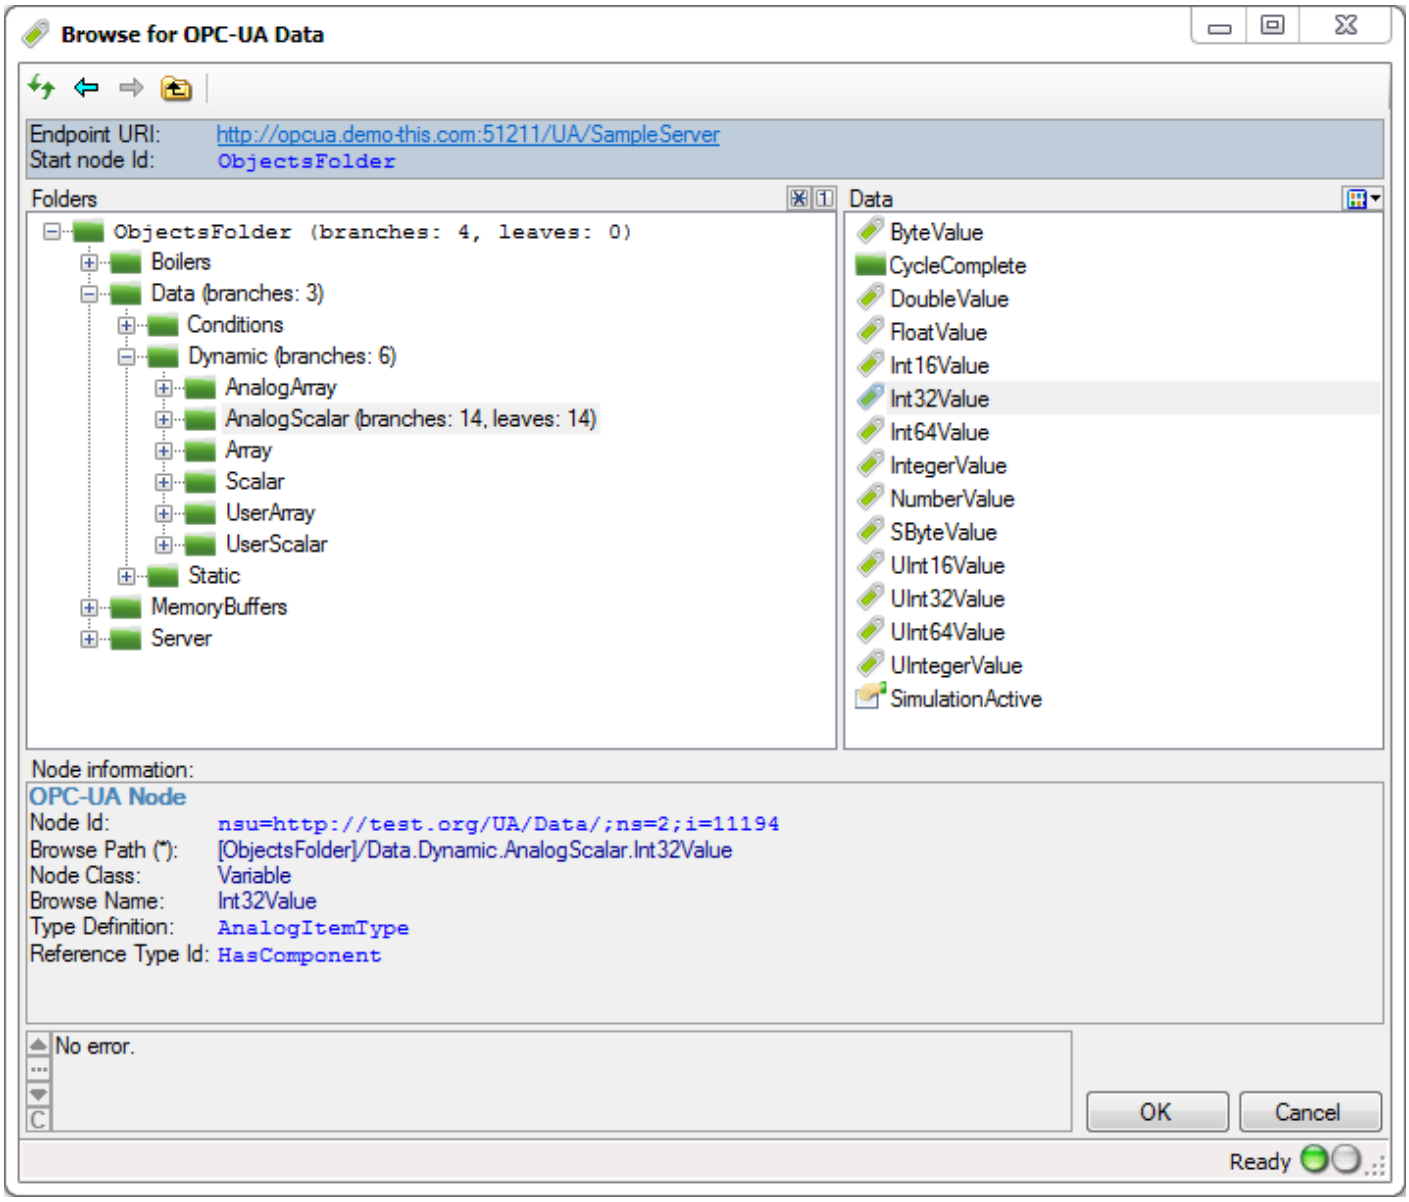
6.1.1.3.3 OPC-UA Data Dialog

Icon: 

The OPC-UA Data Dialog (UADataDialog class) allows the user to interactively select the OPC data node residing in a specific OPC Unified Architecture server. It also has a different mode (controlled by the UserPickEndpoint property) which allows the user to start the node selection by choosing the host and server endpoint first.

In This Topic

Here is an example of OPC-UA Data dialog in action:



In the default mode (when UserPickEndpoint is false), your code should set the EndpointDescriptor property to specify the OPC Unified Architecture server whose nodes are to be browsed. If you want the user to pick the endpoint, set the UserPickEndpoint property to true; in this case, setting the EndpointDescriptor is not needed on input.

After setting the inputs as needed, your code calls the ShowDialog method. If the result is equal to DialogResult.OK, the

user has selected the OPC data node, and information about it can be retrieved from the NodeElement (and also NodeDescriptor) property. If UserPickEndpoint is true, the chosen server endpoint can be retrieved from the EndpointDescriptor property.

The user can browse through the UA Objects, and select from Data Variables or Properties.

C++

```
// This example shows how to let the user browse for an OPC-UA data node (a Data
Variable or a Property).

#include "stdafx.h"    // Includes "QuickOpc.h", and other commonly used files
#include "ShowDialog.h"

namespace _UADataDialog
{
    void ShowDialog::Main()
    {
        // Initialize the COM library
        CoInitializeEx(NULL, COINIT_MULTITHREADED);
        {
            //
            _UADataDialogPtr DataDialogPtr(__uuidof(UADataDialog));

            //
            DataDialogPtr->EndpointDescriptor->UrlString = L"http://opcua.demo-
this.com:51211/UA/SampleServer";
            DataDialogPtr->UserPickEndpoint = true;

            //
            DialogResult dialogResult = DataDialogPtr->ShowDialog(NULL);

            // Display results
            _tprintf(_T("%d\n"), dialogResult);
            _tprintf(_T("EndpointDescriptor: %s\n"), (LPCTSTR)CW2CT(DataDialogPtr-
>EndpointDescriptor->ToString));
            _tprintf(_T("NodeElement: %s\n"), (LPCTSTR)CW2CT(DataDialogPtr-
>NodeElement->ToString));
        }
         // Release all interface pointers BEFORE calling CoUninitialize()
        CoUninitialize();
    }
}
```

Free Pascal

```
// This example shows how to let the user browse for an OPC-UA data node
// (a Data Variable or a Property).

class procedure ShowDialog.Main;
var
  DataDialog: UADataDialog;
begin
  // Instantiate the dialog object
  DataDialog := CoUADataDialog.Create;
```

```
  DataDialog.EndpointDescriptor.UrlString := 'http://opcua.demo-
this.com:51211/UA/SampleServer';
  DataDialog.UserPickEndpoint := True;

  DataDialog.ShowDialog(nil);

  // Display results
  WriteLn('EndpointDescriptor: ', DataDialog.EndpointDescriptor.ToString);
  WriteLn('NodeElement: ', DataDialog.NodeElement.ToString);
end;
```

Object Pascal

```
// This example shows how to let the user browse for an OPC-UA data node
// (a Data Variable or a Property).

class procedure ShowDialog.Main;
var
  DataDialog: OpcLabs_EasyOpcForms_TLB._UADataDialog;
begin
  // Instantiate the dialog object
  DataDialog := CoUADataDialog.Create;

  DataDialog.EndpointDescriptor.UrlString := 'http://opcua.demo-
this.com:51211/UA/SampleServer';
  DataDialog.UserPickEndpoint := True;

  DataDialog.ShowDialog(nil);

  // Display results
  WriteLn('EndpointDescriptor: ', DataDialog.EndpointDescriptor.ToString);
  WriteLn('NodeElement: ', DataDialog.NodeElement.ToString);
end;
```

Visual Basic (VB 6.)

```
Rem This example shows how to let the user browse for an OPC-UA data node (a Data
Variable or a Property).

Private Sub ShowDialog_Main_Command_Click()
    OutputText = ""

    Dim DataDialog As New UADataDialog
    DataDialog.EndpointDescriptor.UrlString = "opc.tcp://opcua.demo-
this.com:51210/UA/SampleServer"
    DataDialog.UserPickEndpoint = True

    Dim DialogResult
    DialogResult = DataDialog.ShowDialog

    ' Display results
    OutputText = OutputText & DialogResult & vbCrLf
    OutputText = OutputText & "EndpointDescriptor: " & DataDialog.EndpointDescriptor &
vbCrLf
    OutputText = OutputText & "NodeElement: " & DataDialog.NodeElement & vbCrLf
End Sub
```

VBScript

```
Rem This example shows how to let the user browse for an OPC-UA data node (a Data
Variable or a Property).

Option Explicit

Const DialogResult_OK = 1

Dim DataDialog: Set DataDialog =
CreateObject("OpcLabs.EasyOpc.UA.Forms.Browsing.UADataDialog")
DataDialog.EndpointDescriptor.UrlString = "http://opcua.demo-
this.com:51211/UA/SampleServer"
DataDialog.UserPickEndpoint = True

Dim dialogResult: dialogResult = DataDialog.ShowDialog
WScript.Echo dialogResult

If dialogResult <> DialogResult_OK Then
    WScript.Quit
End If

' Display results
WScript.Echo "EndpointDescriptor: " & DataDialog.EndpointDescriptor
WScript.Echo "NodeElement: " & DataDialog.NodeElement
```

Multi-selection

When you set the MultiSelect property of the UADataDialog to true, the dialog will allow the user to select any number of OPC-UA nodes. The list below the folders and data nodes (labeled "Selected nodes") contains the set of nodes that the user has selected in the dialog. The user can freely add nodes to this list, or remove them. The selected set is carried over to next invocation of the dialog, unless you change it from the code.

In the multi-selection mode, the set of nodes selected on input (if any) is in the NodeDescriptors property. On the output, the dialog fills the information about selected nodes into the NodeElements property (and updated the NodeDescriptors property as well). If UserPickEndpoint is true, each node may come from a different server. In this case, the EndpointDescriptors array contains the server endpoints for each node in NodeDescriptors, with corresponding indices in both arrays.

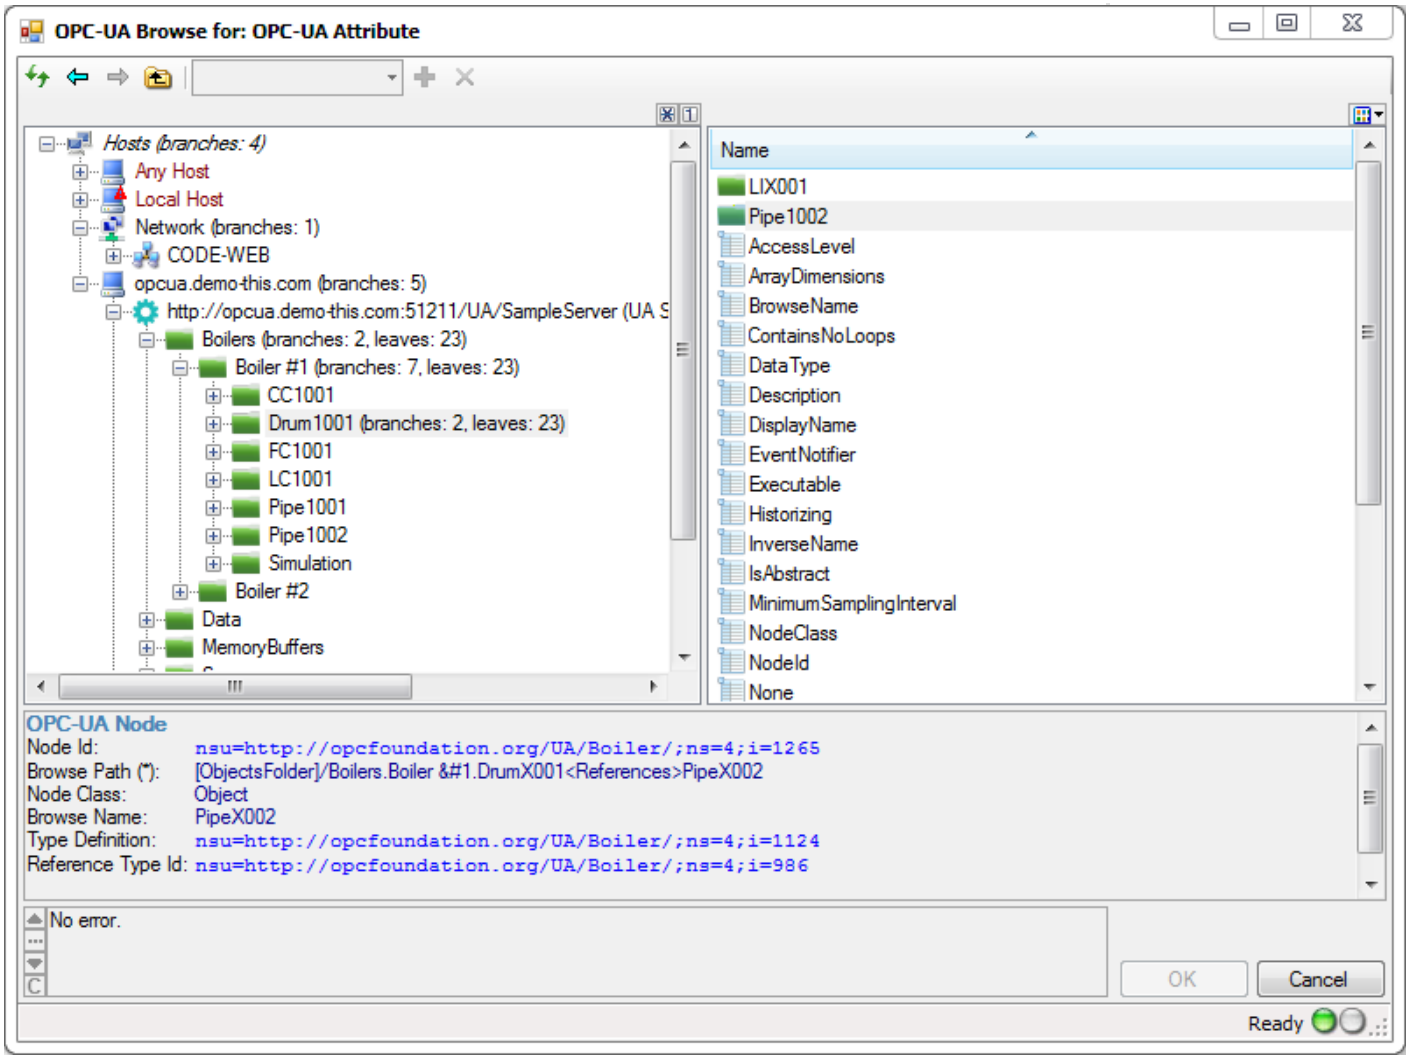
6.1.1.3.4 Generic OPC-UA Browsing Dialog

Icon: 

With UABrowseDialog, your application can integrate a dialog with various OPC-UA elements from which the user can select. This dialog can be configured to serve many different purposes.

Here is an example of the generic OPC-UA browsing dialog in action:

In This Topic

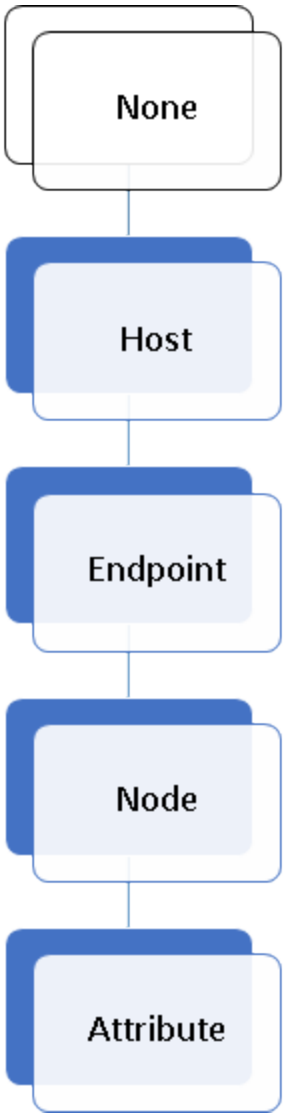


The way the dialog operates is controlled by two main properties:

- Mode.AnchorElementType determines the part of the selection that is given on input and cannot be changed by the user.
- Mode.SelectElementType determines the type of the element that the user needs to select in order to finalize the dialog.

Values of these properties can be selected from the UAElementType enumeration, which has members for various types of elements that you encounter when working with OPC-UA.

The following chart shows a hierarchy of element types that you can choose from:



For example, let' say that you set Mode.AnchorElementType to Endpoint, and Mode.SelectElementType to Attribute. This will cause the dialog to allow the user to browse for an OPC-UA Node on a given server, and then for an OPC-UA attribute on that node.

In this case, before you run the dialog, you need to provide it with values for the InputsOutputs.CurrentNodeDescriptor.EndpointDescriptor property, because those define your "anchor" element (Endpoint) that the user cannot change. The dialog will only allow the user to finalize it (besides cancelling) after an OPC-UA attribute is fully selected, because that is your Mode.SelectElementType. After the dialog is successfully finalized, the information about the user's choice will be available in the Outputs.CurrentNodeElement.NodeElement and InputsOutputs.CurrentNodeDescriptor.AttributeId properties.

Note that in addition to the "minimal" scenario described above, you can also pre-set the initial node or attribute, using the InputsOutputs.CurrentNodeDescriptor.NodeDescriptor or InputsOutputs.CurrentNodeDescriptor.AttributeId properties, and after the selection is made, these properties will be updated to the new selection as well. This way, if you run the dialog again with the same value, the initial selection will be where the user has left it the last time the dialog was run.

Obviously, the chosen Mode.SelectElementType must be a child or indirect ancestor of chosen Mode.AnchorElementType in the hierarchy.

C++

```
// This example shows how to let the user browse for an OPC-UA node.

#include "stdafx.h"    // Includes "QuickOpc.h", and other commonly used files
#include "ShowDialog.h"

namespace _UABrowseDialog
{
    void ShowDialog::Main()
    {
        // Initialize the COM library
        CoInitializeEx(NULL, COINIT_MULTITHREADED);
        {
            //
            _UABrowseDialogPtr BrowseDialogPtr(__uuidof(UABrowseDialog));

            //
            BrowseDialogPtr->InputsOutputs->CurrentNodeDescriptor->EndpointDescriptor-
>Host = L"opcua.demo-this.com";
            BrowseDialogPtr->Mode->AnchorElementType = UAElementType_Host;

            //
            DialogResult dialogResult = BrowseDialogPtr->ShowDialog(NULL);

            // Display results
            _tprintf(_T("%d\n"), dialogResult);
            _tprintf(_T("%s\n"), (LPCTSTR)CW2CT(BrowseDialogPtr->Outputs-
>CurrentNodeElement->NodeElement->ToString));
        }
         // Release all interface pointers BEFORE calling CoUninitialize()
        CoUninitialize();
    }
}
```

Free Pascal

```
// This example shows how to let the user browse for an OPC-UA node.

class procedure ShowDialog.Main;
var
  BrowseDialog: UABrowseDialog;
begin
  // Instantiate the dialog object
  BrowseDialog := CoUABrowseDialog.Create;
  BrowseDialog.InputsOutputs.CurrentNodeDescriptor.EndpointDescriptor.Host :=
'opcua.demo-this.com';
  BrowseDialog.Mode.AnchorElementType := UAElementType_Host;

  BrowseDialog.ShowDialog(nil);

  // Display results
  WriteLn(BrowseDialog.Outputs.CurrentNodeElement.NodeElement.ToString);
end;
```

Object Pascal

```
// This example shows how to let the user browse for an OPC-UA node.

class procedure ShowDialog.Main;
var
  BrowseDialog: OpcLabs_EasyOpcForms_TLB._UABrowseDialog;
begin
  // Instantiate the dialog object
  BrowseDialog := CoUABrowseDialog.Create;
  BrowseDialog.InputsOutputs.CurrentNodeDescriptor.EndpointDescriptor.Host :=
'opcua.demo-this.com';
  BrowseDialog.Mode.AnchorElementType := UAElementType_Host;

  BrowseDialog.ShowDialog(nil);

  // Display results
  WriteLn(BrowseDialog.Outputs.CurrentNodeElement.NodeElement.ToString);
end;
```

PHP

```
// This example shows how to let the user browse for an OPC-UA node.

$UAElementType_Host = 1;

$BrowseDialog = new COM("OpcLabs.EasyOpc.UA.Forms.Browsing.UABrowseDialog");
$BrowseDialog->InputsOutputs->CurrentNodeDescriptor->EndpointDescriptor->Host =
"opcua.demo-this.com";
$BrowseDialog->Mode->AnchorElementType = $UAElementType_Host;

printf("%d\n", $BrowseDialog->ShowDialog);

// Display results
printf("%s\n", $BrowseDialog->Outputs->CurrentNodeElement->NodeElement);
```

Python

```
# This example shows how to let the user browse for an OPC-UA node.

import win32com.client

UAElementType_Host = 1

browseDialog =
win32com.client.Dispatch('OpcLabs.EasyOpc.UA.Forms.Browsing.UABrowseDialog')
browseDialog.InputsOutputs.CurrentNodeDescriptor.EndpointDescriptor.Host = "opcua.demo-
this.com"
browseDialog.Mode.AnchorElementType = UAElementType_Host

print(browseDialog.ShowDialog())

# Display results
print(browseDialog.Outputs.CurrentNodeElement.NodeElement)
```

Visual Basic (VB 6.)

```
Rem This example shows how to let the user browse for an OPC-UA node.

Private Sub ShowDialog_Main_Command_Click()
    OutputText = ""

    Dim BrowseDialog As New UABrowseDialog
    BrowseDialog.InputsOutputs.CurrentNodeDescriptor.EndpointDescriptor.Host =
"opcua.demo-this.com"

    Dim DialogResult
    DialogResult = BrowseDialog.ShowDialog

    ' Display results
    OutputText = OutputText & DialogResult & vbCrLf
    OutputText = OutputText & BrowseDialog.outputs.CurrentNodeElement.NodeElement &
vbCrLf
End Sub
```

VBScript

```
Rem This example shows how to let the user browse for an OPC-UA node.

Option Explicit

Const DialogResult_OK = 1

Const UAElementType_Host = 1

Dim BrowseDialog: Set BrowseDialog =
CreateObject("OpcLabs.EasyOpc.UA.Forms.Browsing.UABrowseDialog")
BrowseDialog.InputsOutputs.CurrentNodeDescriptor.EndpointDescriptor.Host = "opcua.demo-
this.com"
BrowseDialog.Mode.AnchorElementType = UAElementType_Host

Dim dialogResult: dialogResult = BrowseDialog.ShowDialog
WScript.Echo dialogResult

If dialogResult <> DialogResult_OK Then
    WScript.Quit
End If

' Display results
WScript.Echo BrowseDialog.Outputs.CurrentNodeElement.NodeElement
```

Multi-selection

It is also possible to configure the dialog for a multi-selection. In this mode, the user can select zero, one, or more nodes. In order to enable the multi-select mode, set the Mode.MultiSelect property to true. In the multi-select mode, the initial set of the selected nodes (when the dialog is first displayed to the user) is given by the contents of the InputOutputs.SelectionDescriptors collection. When the user makes the selection and accepts it by closing the dialog,

this collection is updated, and also, all information about the selected nodes is placed to the Outputs.SelectionElements collection.

VBScript

```
Rem This example shows how to let the user browse for multiple OPC-UA nodes.

Option Explicit

Const DialogResult_OK = 1

Const UAElementType_Host = 1

Dim BrowseDialog: Set BrowseDialog =
CreateObject("OpcLabs.EasyOpc.UA.Forms.Browsing.UABrowseDialog")
BrowseDialog.InputsOutputs.CurrentNodeDescriptor.EndpointDescriptor.Host = "opcua.demo-
this.com"
BrowseDialog.Mode.AnchorElementType = UAElementType_Host
BrowseDialog.Mode.MultiSelect = True

Dim dialogResult: dialogResult = BrowseDialog.ShowDialog
WScript.Echo dialogResult

If dialogResult <> DialogResult_OK Then
    WScript.Quit
End If

' Display results
Dim SelectionElements: Set SelectionElements = BrowseDialog.Outputs.SelectionElements
Dim i: For i = 0 To SelectionElements.Count - 1
    Dim Element: Set Element = SelectionElements(i)
    WScript.Echo "SelectionElements(" & i & "): " & Element.NodeElement
Next
```

Other settings

There are also ways to control some finer aspects of the dialog. For example, the Mode.ShowListBranches property (defaults to true) controls whether the branches of the tree are also displayed in the list view.

When you set the Simulated property of the dialog to true, the dialog will provide its contents from a pre-defined, simulated view of the world, with fake networks, computers, OPC servers, and their contents. This can be useful for experimentation and testing, either by the developer during the design (right in Visual Studio), or by the end-user (if you expose this functionality in your application), when the environment is not accessible.

6.1.2 OPC Controls

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product

> Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

6.1.2.1 OPC Classic Controls

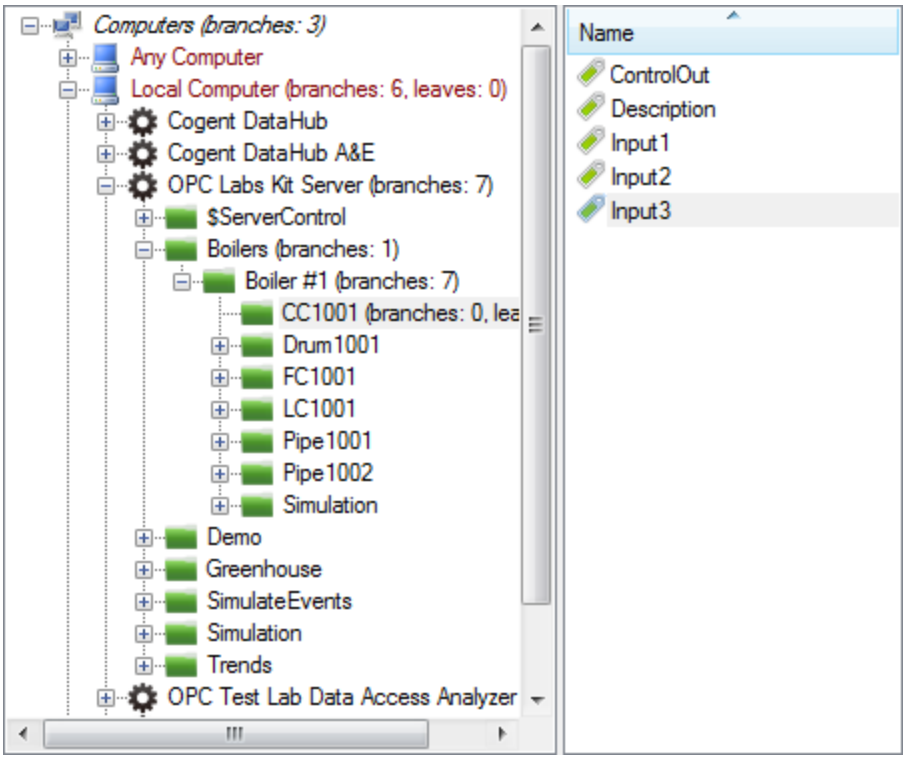
OPC Data Client.NET contains OPC-enabled .NET controls that can be placed onto your Windows Forms and configured and programmed to cooperate with other controls.

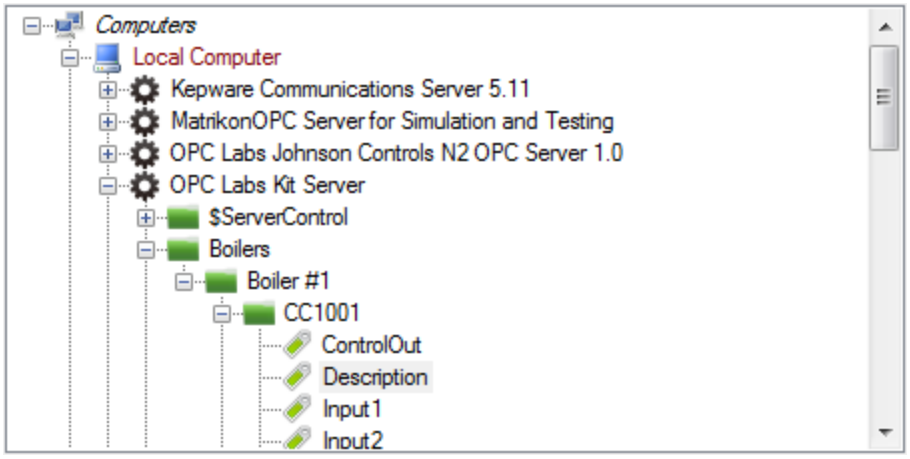
Articles in this section apply to OPC "Classic" DA and OPC XML-DA.

6.1.2.1.1 Generic OPC Classic Browsing Control

With OpcBrowseControl, your forms can integrate a control with various OPC nodes from which the user can select. This control can be configured to serve many different purposes.

Here are examples of the generic OPC browsing control in action:





The functionality and properties of the OpcBrowseControl are similar to that of OpcBrowseDialog, described earlier in this text. Please refer to the documentation of OpcBrowseDialog for details. Here are the major differences:

- There is no toolbar, no filter controls, no node information box, no error box, and no status bar. Events are provided (described further below) that allow you to implement similar functionality yourself, if needed.
- Changes you make in run-time to relevant values of the Inputs and InputsOutputs properties are immediately reflected in the control. Analogically, actions by the user that change the current node or the selection set are immediately projected into the InputsOutputs and Outputs properties.
- When multi-selection mode is enabled, the nodes are always selected directly in the list view, and not in a separate list. For this reason, the nodes in a multi-selection must all belong under a single parent branch.
- If only a tree view is displayed, the tree will also contain the leaves.
- If only a list view is displayed, the list will also always contain the branches, regardless of the Mode.ShowListBranches property value.
- When a node is selected in the tree view, a first node in the list view is not automatically focused.
- In the design-time mode, the control always shows simulated data, even if the Simulated property is set to false.

Using the Kind property, the browsing control can be configured to provide a tree view only (BrowseControlKinds.Tree), a list view only (BrowseControlKinds.List), or a combined tree view and list view (BrowseControlKinds.TreeAndList; this is the default).

The View property (of System.Windows.Forms.View enumeration type) controls how the list view items are displayed. Possible values are LargeIcon, Details (the default), SmallIcon, List, or Tile.

In order to achieve tight integration with other controls on your form, you can hook to events that the browsing control provides.

The CurrentNodeChanged event occurs when the current node changes. You can obtain the information about the new current node from InputsOutputs.CurrentNodeDescriptor and Outputs.CurrentNodeElement properties inside the event handler.

The SelectionChanged event is meant for multi-selection mode, and occurs when the selection set changes. You can obtain the information about the new selection set from InputsOutputs.SelectionDescriptors and Outputs.SelectionElements collections inside the event handler.

The NodeDoubleClick event occurs when a node is double-clicked. This is the current node, and therefore the information about it can be obtained in the same way as in the CurrentNodeChanged event handler, described above.

The BrowseFailure event indicates that an exception has occurred during browsing. The information about the exception is contained in the event arguments.

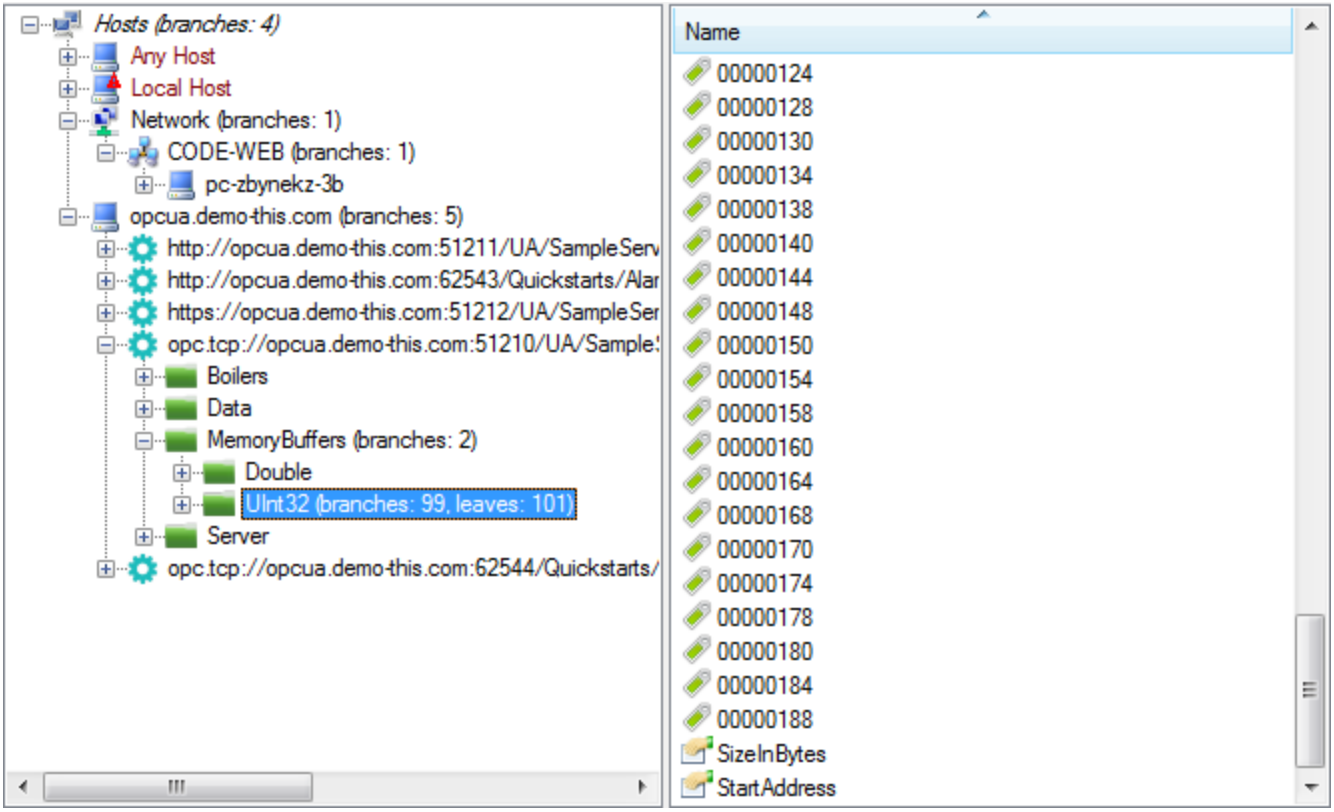
6.1.2.2 OPC-UA Controls

OPC Data Client-UA contains OPC-enabled .NET controls that can be placed onto your Windows Forms and configured and programmed to cooperate with other controls.

6.1.2.2.1 Generic OPC UA Browsing Control

With UABrowseControl, your forms can integrate a control with various OPC nodes from which the user can select. This control can be configured to serve many different purposes.

Here is an example of the generic OPC browsing control in action:



The functionality and properties of the UABrowseControl are similar to that of UABrowseControl, described earlier in this text. Please refer to the documentation of UABrowseControl for details. Here are the major differences:

- There is no toolbar, no filter controls, no node information box, no error box, and no status bar. Events are provided (described further below) that allow you to implement similar functionality yourself, if needed.
- Changes you make in run-time to relevant values of the Inputs and InputsOutputs properties are immediately reflected in the control. Analogically, actions by the user that change the current node or the selection set are immediately projected into the InputsOutputs and Outputs properties.
- When multi-selection mode is enabled, the nodes are always selected directly in the list view, and not in a separate list. For this reason, the nodes in a multi-selection must all belong under a single parent branch.
- If only a tree view is displayed, the tree will also contain the leaves.
- If only a list view is displayed, the list will also always contain the branches, regardless of the Mode.ShowListBranches property value.
- When a node is selected in the tree view, a first node in the list view is not automatically focused.

- In the design-time mode, the control always shows simulated data, even if the Simulated property is set to false.

Using the Kind property, the browsing control can be configured to provide a tree view only (BrowseControlKinds.Tree), a list view only (BrowseControlKinds.List), or a combined tree view and list view (BrowseControlKinds.TreeAndList; this is the default).

The View property (of System.Windows.Forms.View enumeration type) controls how the list view items are displayed. Possible values are LargeIcon, Details (the default), SmallIcon, List, or Tile.

In order to achieve tight integration with other controls on your form, you can hook to events that the browsing control provides.

The CurrentNodeChanged event occurs when the current node changes. You can obtain the information about the new current node from InputsOutputs.CurrentNodeDescriptor and Outputs.CurrentNodeElement properties inside the event handler.

The SelectionChanged event is meant for multi-selection mode, and occurs when the selection set changes. You can obtain the information about the new selection set from InputsOutputs.SelectionDescriptors and Outputs.SelectionElements collections inside the event handler.

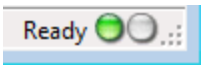
The NodeDoubleClick event occurs when a node is double-clicked. This is the current node, and therefore the information about it can be obtained in the same way as in the CurrentNodeChanged event handler, described above.

The BrowseFailure event indicates that an exception has occurred during browsing. The information about the exception is contained in the event arguments.

6.1.3 Common Functionality in Browsing Dialogs and Controls

The tree view in the browsing dialogs displays the number of node sub-branches and sub-leaves (when known) in the parentheses next to the node name.

The browsing dialogs also have a “traffic light” status indicator in the lower right corner, allowing for quick recognition of the status by the user.



The hierarchical browsing dialogs have Back and Forward buttons, allowing better navigation experience in some scenarios. The buttons behave similarly to those commonly found in Internet browsers.

Depending on the active node, the user can also invoke various context-dependent commands, as described in **Context Commands in Browsing (Section 6.1.3.1)**.

In many browse dialogs and controls, the user can use a Search box to enter the text to search for, choose various search options, and navigate in the tree and/or list to nodes that fulfill the search criteria: **Search in Browsing (Section 6.1.3.2)**.

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product

> Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

6.1.3.1 Context Commands in Browsing

During the browsing, various nodes expose different functionality, depending on their type and settings. The node-specific functionality is made available using context commands, such as those on the node context menu (accessible through the right-click), or in the **Actions** pane of the browsing control.

For a list and description of these commands, depending on the domain, refer to one of the following chapters:

- **Context Commands in OPC Classic Browsing (Section 6.1.3.1.1)**
- **Context Commands in OPC UA Browsing (Section 6.1.3.1.2)**
- **Search in Browsing (Section 6.1.3.2)**

6.1.3.1.1 Context Commands in OPC Classic Browsing

Commands described in this article are available when browsing in the OPC Classic domain.

In This Topic

OPC Computer Node

Troubleshooting: Ping Computer Test

Makes a quick connectivity check to the selected computer. Note that the PING command may fail but the computer may still be accessible via OPC.

OPC Server Node

Duplicate Server Node

Creates a duplicate of an existing OPC server node.

Troubleshooting: Ping Computer Test

Makes a quick connectivity check to the selected computer. Note that the PING command may fail but the computer may still be accessible via OPC.

Troubleshooting: TCP Connect Test

This command attempts to open a TCP socket to the selected endpoint (without any OPC-specific actions or communication), in order to verify the network connectivity and the presence of the server or endpoint.

The command is only enabled on OPC XML-DA server nodes.

6.1.3.1.2 Context Commands in OPC UA Browsing

Commands described in this article are available when browsing in the OPC Unified Architecture (OPC UA) domain.

In This Topic

OPC UA Root Node

Settings: Endpoint Selection Policy

Configures the default endpoint selection policy, valid on endpoints which do not specify their endpoint selection policy explicitly.

Settings: Certificate Acceptance Policy

Globally configures how other-party application certificates are accepted.

Application: View Instance Certificate

Locates, retrieves and displays the application instance certificate currently used by the application.

OPC UA Host Node

Enable Local Discovery

When set, connects to the OPC UA Local Discovery Server (LDS) on the host, and shows the applications and/or discovery endpoints registered on the host.

Troubleshooting: Ping Host Test

Makes a quick connectivity check to the selected host. Note that the PING command may fail but the host may still be accessible via OPC.

Browse As: Applications

Groups the information returned from the OPC UA browsing by OPC UA applications.

Browse As: Discovery Endpoints

Shows the individual OPC UA discovery endpoints returned from the OPC UA browsing.

Discovery Endpoints Display: URL, Application Name

The discovery endpoints are displayed using their URL, with an appended application name in parenthesis. For example: opc.tcp://opcua.demo-this.com:51210/UA/SampleServer (UA Sample Server) .

Discovery Endpoints Display: URL

The discovery endpoints are displayed using their URL only. For example: opc.tcp://opcua.demo-

this.com:51210/UA/SampleServer .

OPC UA Application Node (from local discovery)

Browse As: Discovery Endpoints

Shows the individual OPC UA discovery endpoints returned from the OPC UA browsing.

Browse As: Session Endpoints

Shows session endpoints available for the discovery endpoint or application underneath its node.

Discovery Endpoints Display: URL

The discovery endpoints are displayed using their URL. For example: opc.tcp://opcua.demo-this.com:51210/UA/SampleServer .

Discovery Endpoints Display: Scheme

The session endpoints are displayed using their scheme. For example: http: .

Session Endpoints Display: URL, Policy Specifier

The session endpoints are displayed using their URL (host part may be replaced by "..." if it clear from some ancestor node), and a policy specifier. Example: http://...:51211/UA/SamplesServer - [SignAndEncrypt:Basic128Rsa15:] .

Session Endpoints Display: Scheme, Policy Specifier

The session endpoints are displayed using their scheme, and a policy specifier. For example: http: - [SignAndEncrypt:Basic128Rsa15:] .

Session Endpoints Display: Policy, Mode, Profile

The session endpoints are displayed using their policy name and security mode, with an appended profile name in parenthesis. For example: Basic128Rsa15 - SignAndEncrypt (soaphttp-wssc-uaxml-uabinary) .

OPC UA Application Node (from network or global discovery)

(none)

OPC UA Endpoint Node

Duplicate Endpoint Node

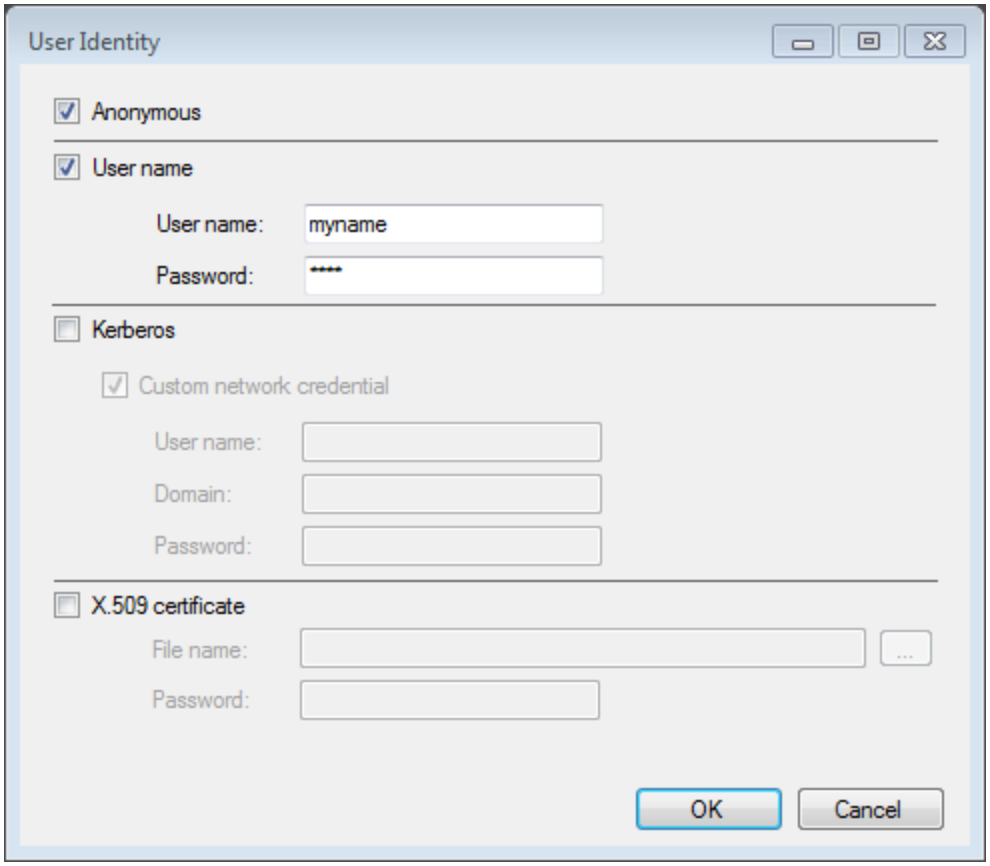
Creates a duplicate of an existing OPC UA endpoint node. By creating a duplicate, you may set parameters of the endpoint (such as endpoint selection policy, or user identity) differently from the original node.

Treat As GDS

When set, treats the endpoint node as OPC UA Global Discovery Server (GDS). In this mode, the applications registered in the GDS are shown underneath the endpoint node (instead of normal OPC UA address space), and additional commands are made available on the node, for GDS registration, Certificate Managemer (CM) operations, etc.

Endpoint Parameters: User Identity

This command allows the user to specify the identity (or identities) that should be used during the connection attempt(s) to the server.



Endpoint Parameters: Endpoint Selection Policy

Allows the user to influence the endpoint selection, specifically for the selected OPC UA endpoint node.

Troubleshooting: Ping Host Test

Makes a quick connectivity check to the selected host. Note that the PING command may fail but the host may still be accessible via OPC.

Troubleshooting: TCP Connect Test

This command attempts to open a TCP socket to the selected endpoint (without any OPC-specific actions or communication), in order to verify the network connectivity and the presence of the server or endpoint.

OPC UA Endpoint Node (discovery endpoint)

Browse As: Session Endpoints

Shows session endpoints available for the discovery endpoint or application underneath its node.

Browse As: Address Space

Shows the address space of the OPC UA server underneath the discovery endpoint node.

Session Endpoints Display: URL, Policy Specifier

The session endpoints are displayed using their URL (host part may be replaced by "..." if it clear from some ancestor node), and a policy specifier. Example: http://...:51211/UA/SamplesServer - [SignAndEncrypt:Basic128Rsa15:] .

Session Endpoints Display: Scheme, Policy Specifier

The session endpoints are displayed using their scheme, and a policy specifier. For example: http: - [SignAndEncrypt:Basic128Rsa15:] .

Session Endpoints Display: Policy, Mode, Profile

The session endpoints are displayed using their policy name and security mode, with an appended profile name in parenthesis. For example: Basic128Rsa15 - SignAndEncrypt (soaphttp-wssc-uaxml-uabinary) .

OPC UA Endpoint Node (with Treat As GDS)

GDS Registration: Register This Client

Creates an application registration in the GDS, assigning it a new application ID. Existing registrations with the same application URI are removed first.

GDS Registration: Update This Client Registration

Updates an application registration in the GDS, keeping its application ID. A new registration is created if the application is not yet registered in the GDS. Preexisting registrations with the same application URI are removed.

GDS Registration: Unregister This Client

Removes an application registration from the GDS, if it exists. All existing registrations for the application URI are removed.

GDS Registration: Find This Client Registrations

Finds and displays all registrations for this application URI in the GDS.

Certificate Manager (CM): Obtain New Certificate

Obtains a new application instance certificate from the certificate manager, and stores it for subsequent usage.

Certificate Manager (CM): Refresh Own Trust Lists

Retrieves the current trust lists for the application from the certificate manager, and refreshes own certificate stores

accordingly.

OPC UA Network Node

Enable Network Discovery

When set, connects to the OPC UA Local Discovery Server with Multicast Extensions (LDS-ME) on the host, and shows the hosts, applications and/or discovery endpoints on the host's network.

Troubleshooting: Ping Host Test

Makes a quick connectivity check to the selected host. Note that the PING command may fail but the host may still be accessible via OPC.

Browse As: Hosts

Groups the information returned from the OPC UA network browsing by hosts.

Browse As: Applications

Groups the information returned from the OPC UA browsing by OPC UA applications.

Browse As: Discovery Endpoints

Shows the individual OPC UA discovery endpoints returned from the OPC UA browsing.

Discovery Endpoints Display: URL, Application Name

The discovery endpoints are displayed using their URL, with an appended application name in parenthesis. For example: opc.tcp://opcua.demo-this.com:51210/UA/SampleServer (UA Sample Server) .

Discovery Endpoints Display: URL

The discovery endpoints are displayed using their URL only. For example: opc.tcp://opcua.demo-this.com:51210/UA/SampleServer .

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

6.1.3.2 Search in Browsing

The Search box in the browsing dialogs and controls allows the user to enter text to search for, choose various search options, and navigate in the tree and/or list to nodes that fulfill the search criteria.

In order to find a node, type the text you want to find into the Search box (over the "Find..." text, if the box is otherwise

empty). The Search box contains following icons:

- **Magnifier**: Clicking on it will search for (and highlight) all matching nodes in the tree/list. The currently selected node is not moved.
- **Left arrow** (***Shift+F3***): Searches for and highlights all matching nodes, and select the previous matching node. When typing, ***Shift+Enter*** has the same meaning.
- **Right arrow** (***F3***): Searches for and highlights all matching nodes, and select the next matching node. When typing, ***Enter*** has the same meaning.
- **Blue cross**: Clears the text in the search box, and removes all node highlighting.

The "*x*/*y*" indicator tells the user how many matching nodes have been found (*y*) and the position of the current node in them (*x*).

The Search box has a drop-down menu with additional commands. You can invoke the drop-down menu by clicking on the down-arrow box, or by pressing a ***down arrow*** key whil typing. The drop-down menu is divided into 3 parts:

1. **Find**. Contains a list of 10 recently used search texts, together with an icon indicating their search type. Selecting any of these commands repeats the corresponding search.
2. **Find options**. Allows to influence how the search is being performed. Available options are Starts with/End with/Contains/Does not contain/Precise text, Match case, and Regular expression.
3. **Nodes**. Contains a list of all nodes that fulfill the search criteria. Selecting any of these commands sets the corresponding node as a currently selected ndoe in the tree/list.

6.1.4 Unsolicited User Interaction

Introduction

OPC Data Client components may, under certain circumstances, display a user interface "by itself", without you having to make a specific method call. Such unsolicited user interaction only happens when the current process is running in user interactive mode, as reported by the Environment.UserInteractive Property. In non-interactive mode, the components assume reasonable default user responses. In addition, you can turn off specific user interactions by setting corresponding parameters in the code.

Usually, these are notifications or confirmations related to conditions that cannot be anticipated upfront, such as the certificate exchange in the OPC UA connection process. As OPC Data Client controls the connections and diconnections automatically, and when subscriptions are in effect, also makes re-connections, you - as a developer - cannot generally predict when such user interaction may be needed.

Interaction Types

There are following situations that may trigger an unsolicited user interaction related to OPC Unified Architecture (OPC UA) operations:

- Issues while checking or creating an application instance certificate. These are rare, and usually only happen when

the application runs for the first time. These can be turned off or on by the AllowClientCertificatePrompt Property of the EngineParameters Property of EasyUAClient.SharedParameters Property. See also **Providing OPC UA Client Instance Certificate (Section 4.13.1.1)**.

- When HTTPS communication is used, failed validation of server's HTTPS certificate. The user is prompted whether he/she wants to accept the certificate anyway. This prompt can be turned off or on by the AllowUserAcceptCertificate Property of HttpsCertificateAcceptancePolicy Property of EngineParameters Property of EasyUAClient.SharedParameters Property. See also **Trusting OPC UA Server HTTPS Certificate (Section 4.13.1.3)**.
- Failed validation of OPC UA server's instance certificate. The user is prompted whether he/she wants to accept the certificate anyway. This prompt can be turned off or on by the AllowUserAcceptCertificate Property of CertificateAcceptancePolicy Property of EngineParameters Property of EasyUAClient.SharedParameters Property. Alternatively, the certificate acceptance policy can be overridden for a specific endpoint by setting it to a non-null value in CertificateAcceptancePolicy Property. See also **Trusting OPC UA Server Instance Certificate (Section 4.13.1.2)**.
- The effective host name in endpoint URL returned by the server does not match any of the domain names in the server certificate. This may be an indication of a spoofing attempt. The user is prompted whether he/she wants to allow the endpoint anyway. This prompt can be turned off or on by the AllowEndpointDomainPrompt Property of UAClientSessionParameters Class.

There is no unsolicited user interaction related to OPC Classic operations.

Interaction Providers

The way OPC Data Client presents the unsolicited user interaction depends on the environment your application is running in. There is an *interaction provider* for each such supported environment. OPC Data Client interrogates the available interaction providers to see which one should perform the interaction, selects the appropriate interaction provider and then uses it to actually communicate with the user. Following interaction providers are available:

- **Console Interaction Provider**. Used in console applications.
- **Windows Forms Interaction Provider (not in .NET Standard)**. Used on Microsoft Windows in applications that have windowed user interface.
- **Null Interaction Provider**. This provider is used if OPC Data Client cannot find any other interaction provider for the current environment.

Each interaction provider (except for the Null Interaction Provider) can be turned on or off, and may have additional configurable parameters.

Interaction and Blocking

All unsolicited user interaction (with exception of rare messages and confirmations related to client application instance certificate checks) has a timeout associated with it, and a default user response is assumed should the user not respond in time. This means that under normal circumstances, the current activity cannot be blocked indefinitely if the user fails to respond. In fact, this behavior also guarantees that the activity will eventually proceed even if the Environment.UserInteractive Property incorrectly claimed that the process is running in user interactive mode. The timeout is configurable by the AcceptNotificationTimeout Property in the UAUserInteractionParameters Class. In order to obtain or modify this parameter, access the UserInteractionParameters Property of EngineParameters Property of EasyUAClient.SharedParameters Property.

Interaction and Licensing

OPC Data Client components do not display, by itself, any visual warning when there is a problem with the license key, or when the trial license runtime expires. Instead, such problems are reported as other errors, using the channels for the programming model used. For example, in **Imperative Programming Model (Section 5.1)**, the single-argument method throws an exception, a multiple-argument method returns the error in the Exception Property of the OperationResult Class, or with subscriptions, the error is reported in the Exception Property of the OperationEventArgs Class. It is up to the calling code to handle such situations.

6.1.4.1 Console Interaction

Introduction

In This Topic

The Console Interaction Provider uses standard console, available on most systems, for user input and output.

OPC Data Client uses the Console Interaction Provider whenever the Environment.UserInteractive Property returns true, and the **Windows Forms Interaction (Section 6.1.4.2)** Provider does not take precedence. Note that is is also possible to use the **Windows Forms Interaction (Section 6.1.4.2)** in console applications **(not in .NET Standard)**, by referencing the **EasyOpcForms** assembly in the console-based project.

Example Interactions

The example below triggers the component to ask the user whether he/she wants to accept the server's HTTPS certificate.

C#

```
// This example shows how in a console application, the user is asked to accept a server HTTPS certificate.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.Interaction
{
    partial class AcceptCertificate
    {
        public static void Https()
        {
            // Do not implicitly trust any endpoint URLs. We want the user be asked explicitly.
            EasyUAClient.SharedParameters.EngineParameters.CertificateAcceptancePolicy.TrustedEndpointUrlStrings.Clear();

            // Define which server we will work with.
            UAEndpointDescriptor endpointDescriptor = "https://opcua.demo-this.com:51212/UA/SampleServer/";

            // Instantiate the client object.
            var client = new EasyUAClient();

            UAAttributeData attributeData;
            try
            {
                // Obtain attribute data.
                // The component automatically triggers the necessary user interaction during the first operation.
                attributeData = client.Read(endpointDescriptor, "nsu=http://test.org/UA/Data/;i=10853");
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}", uaException.GetBaseException().Message);
                return;
            }

            // Display results.
            Console.WriteLine("Value: {0}", attributeData.Value);
            Console.WriteLine("ServerTimestamp: {0}", attributeData.ServerTimestamp);
            Console.WriteLine("SourceTimestamp: {0}", attributeData.SourceTimestamp);
            Console.WriteLine("StatusCode: {0}", attributeData.StatusCode);
        }
    }
}
```

Object Pascal

```
// This example shows how in a console application, the user is asked to accept a server HTTPS certificate.
```

```
class procedure AcceptCertificate.Https;
var
  AttributeData: _UAAttributeData;
  Client: OpcLabs_EasyOpcUA_TLB._EasyUAClient;
  ClientConfiguration: TEasyUAClientConfiguration;
  EndpointDescriptor: string;
begin
  // The configuration object allows access to static behavior.
  ClientConfiguration := TEasyUAClientConfiguration.Create(nil);
  ClientConfiguration.Connect;

  // Do not implicitly trust any endpoint URLs. We want the user be asked explicitly.
  ClientConfiguration.SharedParameters.EngineParameters.CertificateAcceptancePolicy.TrustedEndpointUrlStrings.Clear();

  // Define which server we will work with.
  EndpointDescriptor := 'https://opcua.demo-this.com:51212/UA/SampleServer/';

  // Instantiate the client object.
  Client := CoEasyUAClient.Create;
  try
    // Obtain attribute data.
    // The component automatically triggers the necessary user interaction during the first operation.
    AttributeData := Client.Read(EndpointDescriptor, 'nsu=http://test.org/UA/Data/;i=10853');
  except
    on E: EOleException do
    begin
      WriteLn(Format('*** Failure: %s', [E.GetBaseException.Message]));
      Exit;
    end;
  end;

  // Display results.
  WriteLn('Value: ', AttributeData.Value);
  WriteLn('ServerTimestamp: ', DateTimeToStr(AttributeData.ServerTimestamp));
  WriteLn('SourceTimestamp: ', DateTimeToStr(AttributeData.SourceTimestamp));
  WriteLn('StatusCode: ', AttributeData.StatusCode.ToString);

  FreeAndNil(ClientConfiguration);
end;
```

VB.NET

```
' This example shows how in a console application, the user is asked to accept a server HTTPS certificate.

Imports OpcLabs.EasyOpc.UA
Imports OpcLabs.EasyOpc.UA.OperationModel

Namespace UADocExamples.Interaction
    Partial Friend Class AcceptCertificate
        Public Shared Sub Https()

            ' Do not implicitly trust any endpoint URLs. We want the user be asked explicitly.
            EasyUAClient.SharedParameters.EngineParameters.CertificateAcceptancePolicy.TrustedEndpointUrlStrings.Clear()

            ' Define which server we will work with.
            Dim endpointDescriptor As UAEndpointDescriptor = "https://opcua.demo-this.com:51212/UA/SampleServer/"

            ' Instantiate the client object.
            Dim client = New EasyUAClient()

            Dim attributeData As UAAttributeData
            Try
                ' Obtain attribute data.
                ' The component automatically triggers the necessary user interaction during the first operation.
                attributeData = client.Read(endpointDescriptor, "nsu=http://test.org/UA/Data/;i=10853")
            Catch uaException As UAException
                Console.WriteLine("*** Failure: {0}", uaException.GetBaseException.Message)
                Exit Sub
            End Try

            ' Display results.
            Console.WriteLine("Value: {0}", attributeData.Value)
            Console.WriteLine("ServerTimestamp: {0}", attributeData.ServerTimestamp)
            Console.WriteLine("SourceTimestamp: {0}", attributeData.SourceTimestamp)
            Console.WriteLine("StatusCode: {0}", attributeData.StatusCode)
        End Sub
    End Class
End Namespace
```

The program output may look like this:

The example below triggers the component to ask the user whether he/she wants to accept the server's instance certificate.

C#

```
// This example shows how in a console application, the user is asked to accept a server instance certificate.

using System;

'StatusCode: Good
```

The program output may look like this:

Configuration

You can configure parameters of the Console Interaction by finding UAConsoleInteractionPluginParameters in the shared plug-ins configurations, and changing properties of the object obtained.

The example below configures the component to use uncolorized console output, and then triggers some user interaction.

C#

```
// Shows how to configure the OPC UA Console Interaction plug-in by turning off the output colorization.

using System;
using System.Diagnostics;
using OpcLabs.BaseLib.Console.Interaction;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.Engine;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.Interaction
{
    partial class ConsoleInteraction
    {
        public static void ColorizeOutput()
        {
            // Configure the shared plug-in.

            // Find the parameters object of the plug-in.
            ConsoleInteractionParameters consoleInteractionPluginParameters =
                EasyUAClient.SharedParameters.PluginConfigurations.Find<ConsoleInteractionParameters>();

The program output may look like this:

6.1.4.2 Windows Forms Interaction

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

In This Topic

Introduction

The Windows Forms Interaction Provider uses windowed user interface on Microsoft Windows operating systems for user input and output.

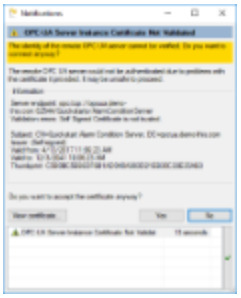
OPC Data Client uses the Windows Forms Interaction Provider whenever the Environment.UserInteractive Property returns true, and the **OpcLabs.EasyOpcForms** assembly can be loaded (which is usually achieved by simply referencing it in your project).

Despite the "Windows Forms" in its name, this interaction provider can also be used in applications that are not based on Windows Forms - for example, in WPF applications, or in applications under COM platform. It is even possible to use it in console applications, in which case the console interaction of your application will be combined with graphical UI pop-ups from the Windows Forms Interaction Provider.

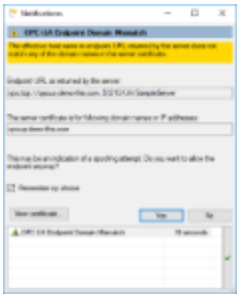
Examples

Accept HTTPS certificate:

Accept instance certificate:



Allow endpoint domain:



Configuration

You can configure parameters of the Windows Forms Interaction by finding UAConsoleInteractionPluginParameters in the shared plug-ins configurations, and changing properties of the object obtained.

6.2 Connectivity Model

The connectivity model is highly generalized, abstract model that allows communication with variuos data sources, without having to know upfront about their implementation details.

If you know ODBC, OLE DB or such technologies for database access, then you can think of Connectivity Model as a similar technology, but for live data, such as in industrial automation or related sectors.

OPC Data Client currently does not make the programmatic access (API) to the Connectivity Model public. The Connectivity Model is, however, on the basis of **Live Binding Model (Section 5.3)**, **Connectivity Explorer (Section 11.2)** tool, and **Excel Option (Section 12.1)** (RTD Server). All these OPC Data Client parts share the features provided by the Connectivity Model, and take advantage from the fact that the model hides the differences between the supported connectivities, such as OPC Classic or OPC Unified Architecture.

6.2.1 Connectivities

The *connectivity* is a component that provides access to a data source of some kind. It can (and usually does) support reading, writing, subscriptions, and browsing.

Three connectivity components are currently provided with OPC Data Client: The DAConnectivity (for OPC Data Access and OPC XML-DA), the UAConnectivity (for OPC Unified Architecture), and the CompositeConnectivity (can be configured to contain and combine any number of other different connectivity components).

6.2.2 Points

Each connectivity must somehow identify the pieces of data it works with. We call them *points*. A connectivity can work with one or more types of points. The composite connectivity merges together the point types of multiple constituent connectivities.

For OPC Data Access (with the DAConnectivity component), following types of points exist:

- DAItemPoint: A point for OPC-DA items.
- DAPropertyPoint: A point for OPC-DA properties (on OPC items).

For OPC Unified Architecture (with the UAConnectivity component), the following point type exists:

- UAAttributePoint: A point for OPC-UA data (node attributes).

> Note: Not all point types have the same capabilities. For example, the most common usage of **Live Binding Model (Section 5.3)**, **Connectivity Explorer (Section 11.2)** tool or the **Excel Option (Section 12.1)** (RTD Server) is with subscriptions (to changing value). Because OPC-DA properties (as opposed to OPC-DA items) do not support subscriptions and we do not emulate them, the subscription operation on OPC-DA property points behaves as a single "get" of the property value.

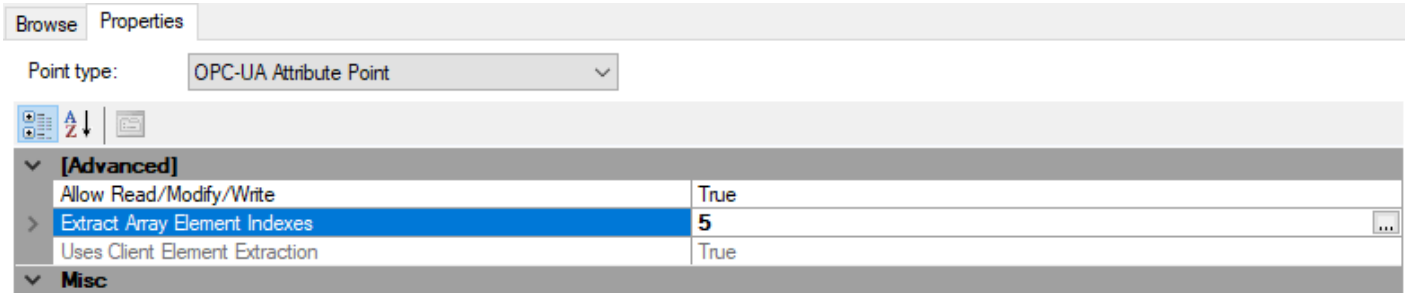
6.2.2.1 Element Extraction

On some points (currently, on all point available: OPC-DA Item Point, OPC-DA Property Point, and OPC-UA Attribute Point), it is possible to use client-side array element extraction.

For array values, this allows you to work with just one element at the given position. With each point, you can specify an index or a list of indices in the ExtractArrayElementIndexes property, and for reads and subscriptions, OPC Data Client will extract the specified element.

In This Topic

Here is how the client-side element extraction is configured in the property grid (the **Properties** tab of the **Point Editor (Section 6.2.3)**).



In the "Extract Array Element Indices" row, you can either manually enter an index or a sequence of indices separated by commas, or you can press the "..." button on the right side to invoke a Collection Editor for the indices.

The client-side array element extraction is mainly useful with OPC Data Access "Classic" servers, because OPC-DA has no corresponding feature in the specification. In OPC Unified Architecture, on the other hand, it is possible to specify Index Range List with each each read, subscribe, or write. If supported, using the Index Range List in OPC UA is recommended over the client-side array element extraction. But not all OPC UA servers support this feature, and in such case you may want to extract the array elements on the client side.

The number of specified indices must match the rank (number of dimensions) of the array, and you can only extract one element (not a range of elements), otherwise an error occurrs.

Reads and Subscriptions

For reads and subscriptions, OPC Data Client will simply read or subscribe to the whole array, and extract the specified element.

Writes

For writes, OPC Data Client will first read the whole array, then modify the element, and then write the whole array back. This read/modify/write algorithm is potentially dangerous if the values are changing in the server or from other clients, and can be disabled using the AllowReadModifyWrite property (defaults to true). When this is disabled and client-side element extraction is specified, the point becomes read-only.

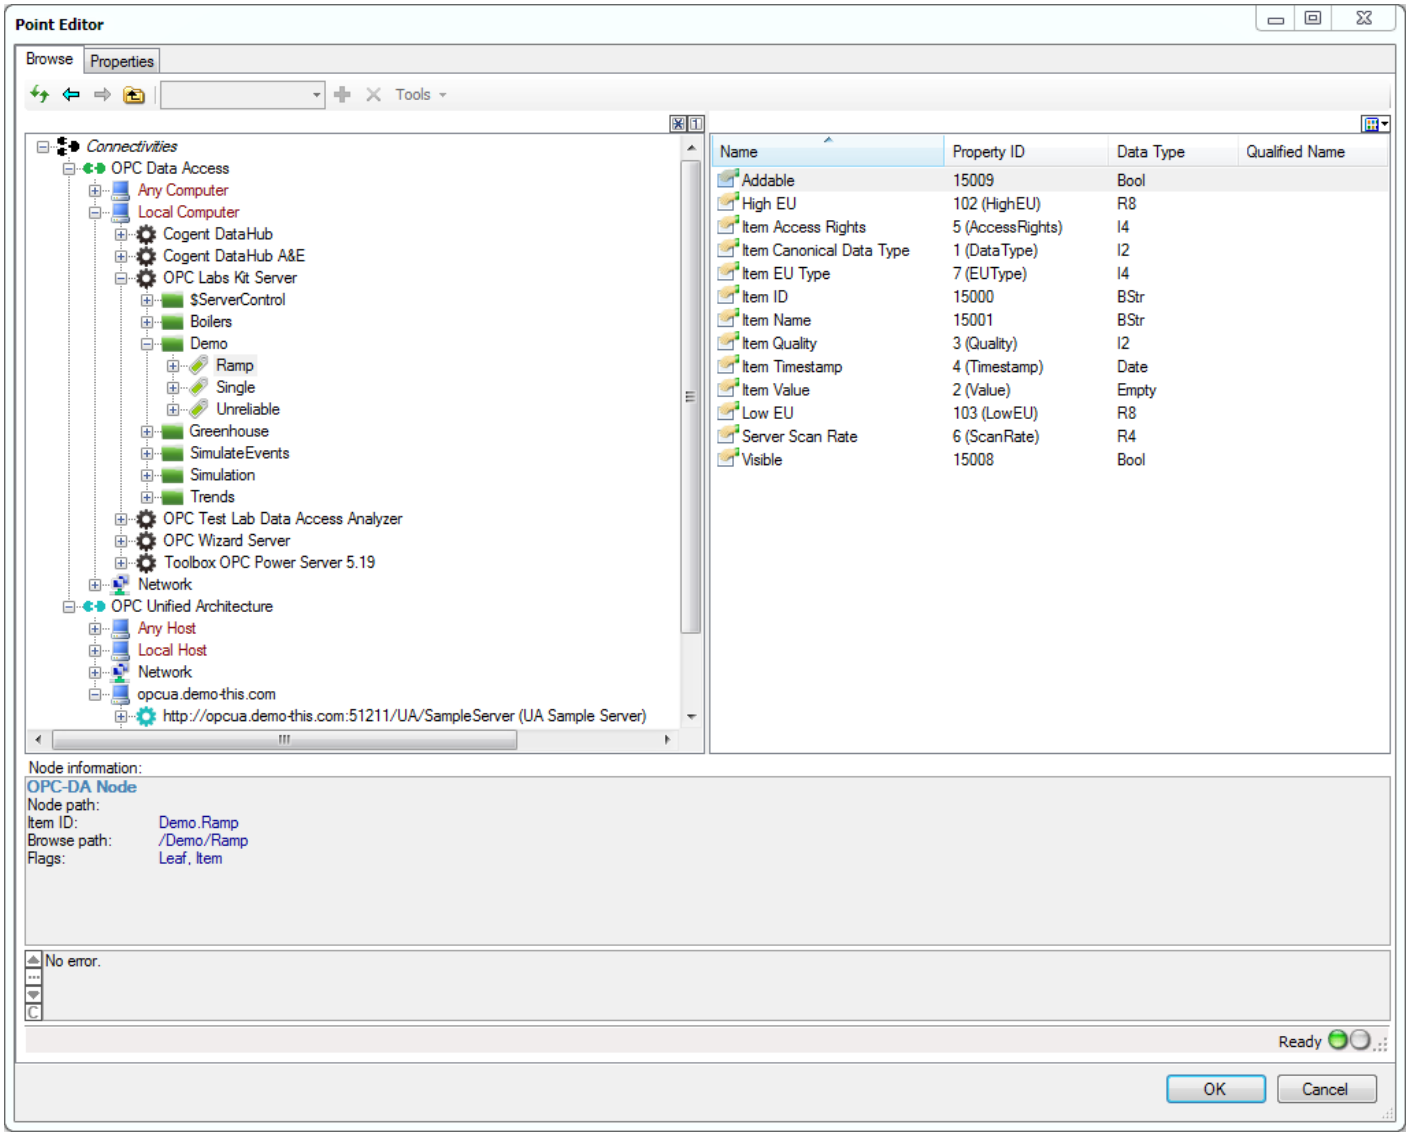
> ⚠ Currently, if you use the element extraction multiple times on the same "underlying" point, OPC Data Client provides no optimization. This means that even if you configure e.g. a point with several different indices, it will be read or subscribed to multiple times. This effect will be mostly noticeable with OPC UA Connectivity, because it currently does not merge together equivalent or similar subscriptions. For writes, each such point will make its own write operation, possibly overwriting the other result(s) if writes are perfomed at once.

6.2.3 Point Editor

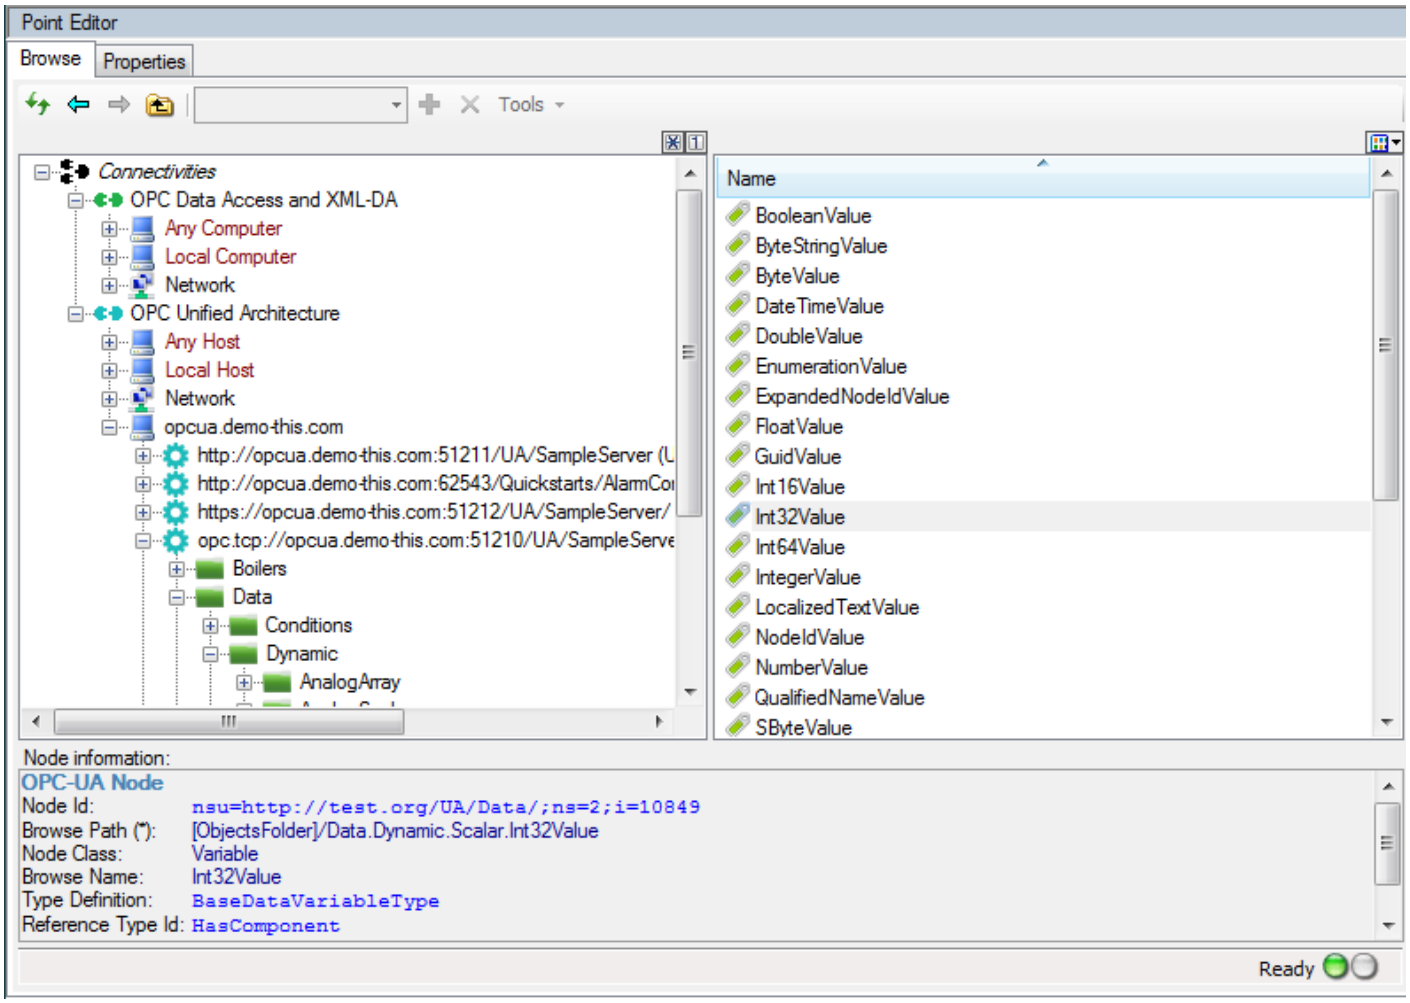
When you are working with the Connectivity Model (such as with the Live Binding in Visual Studio designer, or the Connectivity Explorer tool), you often need to specify the point you'd like to bind to or display.

For this purpose, you will use the **Point Editor**. The Point Editor can be a modal dialog (e.g. in Live Binding), or a subwindow in a larger set (as e.g. in Connectivity Explorer tool), but its main parts are always the same; what differs is the "framing".

In Live Binding, a **Point Editor** dialog is displayed. An example of it is on the following picture:



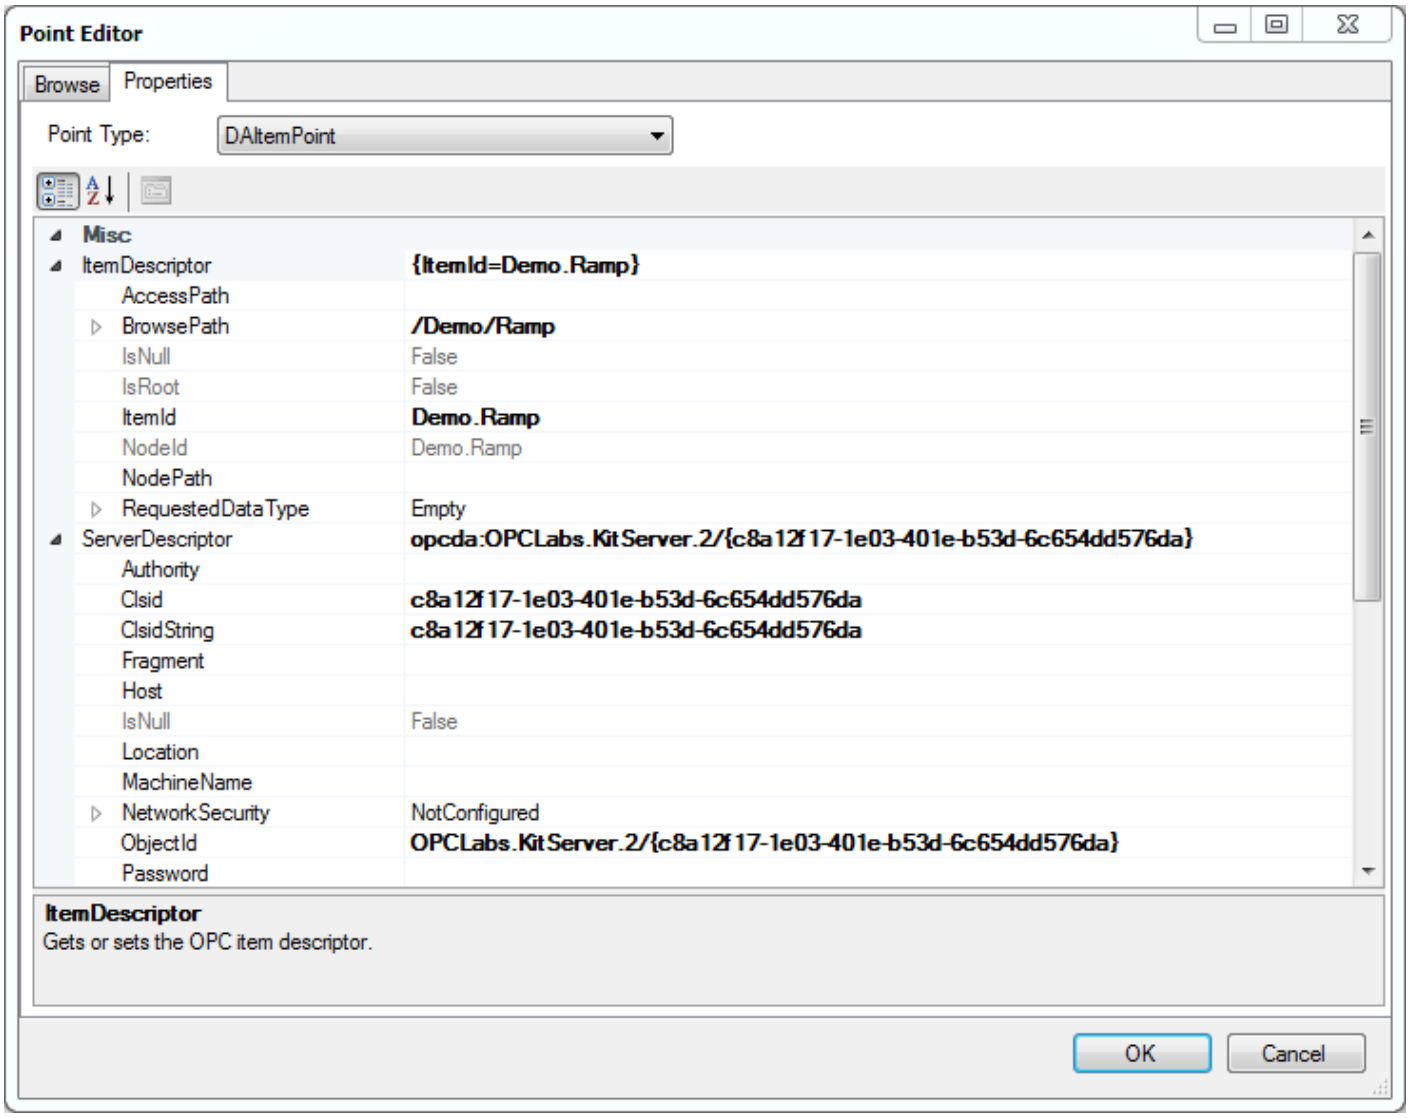
In Connectivity Explorer tool, the main window contains a **Point Editor** subwindow. An example of it is on the following picture:



The actual contents of the dialog or window will of course differ, depending on your configuration. This particular example is with a composite connectivity configured with both OPC Data Access and OPC Unified Architecture, showing multiple binding possibilities in the same dialog.

The point editor has two tabs, labeled **Browse** and **Properties**. Initially, the **Browse** tab is selected, and you are given an opportunity to browse the network, the OPC servers present, and the nodes in them. You can simply select the desired node and press OK (in Live Binding) or double-click on it (in Connectivity Explorer tool).

Sometimes the browsing is not possible, or you may need to view and possibly the details of the selected point. In such cases, you can switch to the **Properties** tab of the dialog:



In the **Properties** tab, the data that describe the point are displayed in a detailed property grid. In addition, in the upper part of the tab, you can select any type of point supported by the connectivity in use, and then fill in its properties as needed.

6.2.3.1 Browse Tab

The **Browse** tab is selected initially (see picture in the **Point Editor (Section 6.2.3)**), and you are given an opportunity to browse the network, the OPC servers present, and the nodes in them. You can simply select the desired node from the tree or list.

If yo do not see the entities you are looking for, you can enter some of them manually. For example, you can enter Computer or Host, and OPC Server or OPC-UA Endpoint.

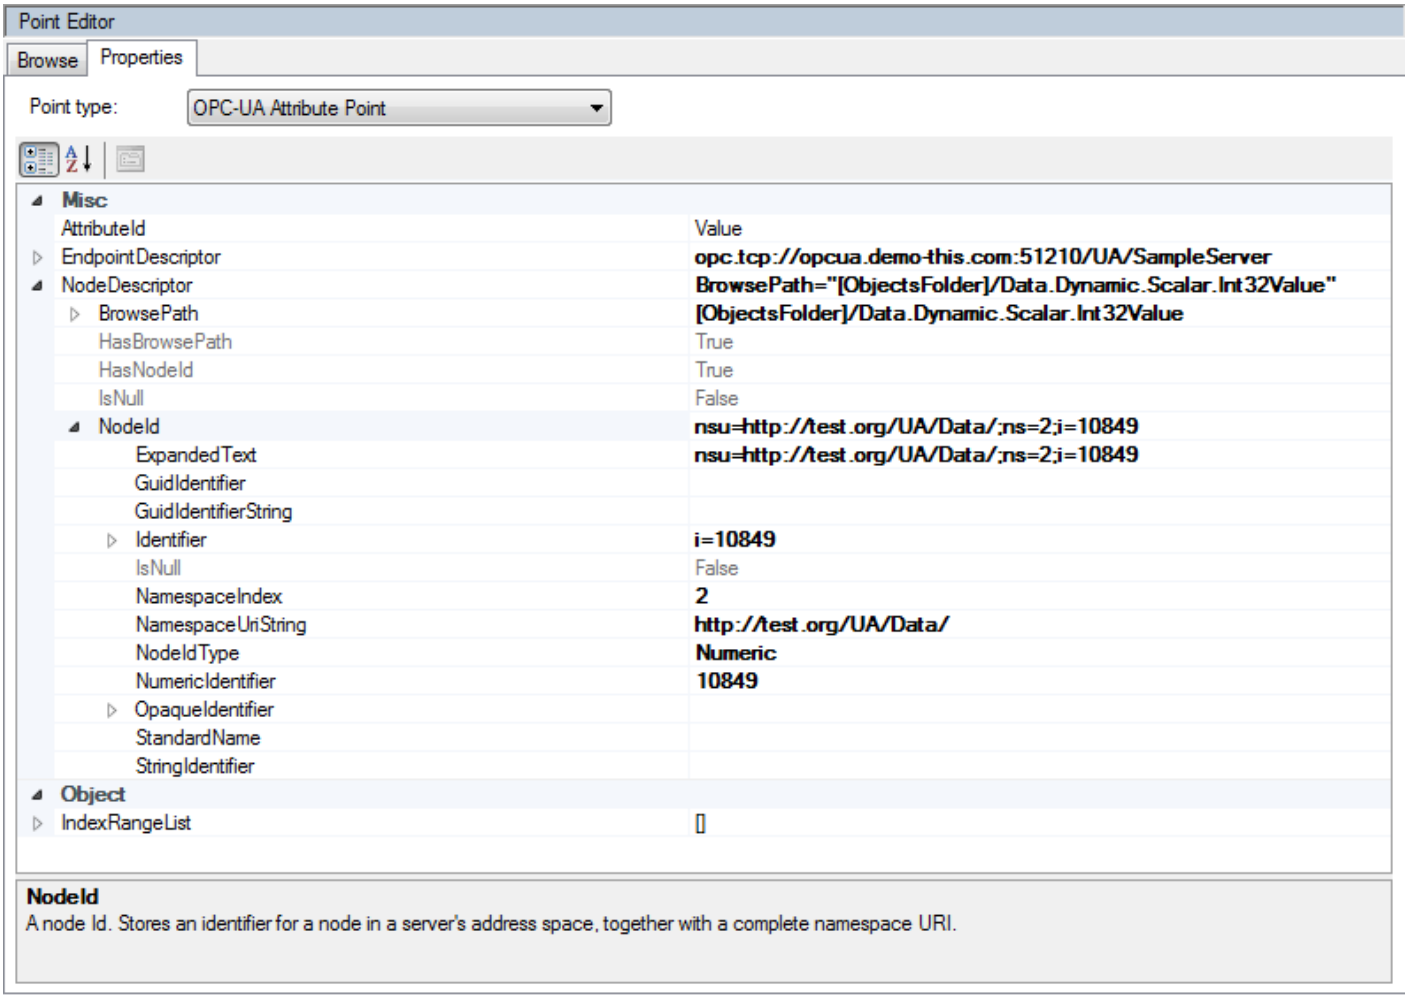
You can also add "Index Range List (OPC-UA)" nodes in the Point Editor. This makes it easier to specify points with index ranges. You do not have to switch into the **Properties** tab, click "..." in the "Index Range List" row, and then "Add" each index range and enter its index values. Instead, simply "Add" the "Index Range List (OPC-UA)" under any OPC UA node,

and then type in the required index range(s), e.g. "5:10".

The **Browse** tab also has a **Legend** pane, allowing the user to view the list of node icons used in the control, and their meaning (descriptions). The **Legend** pane can be turned off and on from the **Layout** menu of the browse control.

6.2.3.2 Properties Tab

In the **Properties** tab, the data that describe the point are displayed in a detailed property grid. In addition, in the upper part of the tab, you can select any type of point supported by the connectivity in use, and then fill in its properties as needed.



6.2.4 Parameters

While the point determines basically the location of the data, *parameters* determine how the data will be accessed. Some operations do not need parameters (in such cases they still exist, but are empty), but most do. For example, a subscription

typically has some kind of update rate as its parameter.

The parameters may depend on the type of point, and the operation involved. A typical connectivity that supports reading, writing and subscription will therefore have up to three types of parameters for each type of point: Read parameters, write parameters, and subscription parameters.

The parameters are not part of the point itself, and are therefore not selected with it in the Point Editor. They are part of the binding (in **Live Binding Model (Section 5.3)**) or data row definitions (in **Connectivity Explorer (Section 11.2)** tool).

6.2.5 Arguments and Results

The *arguments* are the actual data the operation on a connectivity transfers, i.e. the "what". Typically and most importantly, arguments contain the data value being read or written or obtained through subscription.

As with the parameters, they usually depend on the type of point, and the operation involved.

Arguments are represented by an object that has properties, divided into several categories. The categories are as follows:

- **Input**: The data that is taken from the target and provided to the operation (for example, a value to be written).
- **Output**: The data that is obtained by the operation and stored into the target (for example, the value read).
- **Input/Output**: A combination of an input and an output argument.
- **Result**: The result of the operation (for example, the error ID returned).

There is an important distinction between the *outputs*, and the *results*. Each operation can be either successful, or not. When the operation completes, the result arguments are always available. The outputs, however, are only available when the operation succeeded.

6.3 Services

OPC Data Client services are functionality sets that are complementary to the main task of the component. They provide features that are not directly derived from the underlying communication methods of the component, but rather have to do with its integration to the environment, instrumentation (such as configuration), licensing etc.

In This Topic

> ⚠ The term *service* is quite overloaded. It can mean different things in different context. For example, there are *OPC UA services*, which are basically method calls on the OPC UA protocol level. And there are *Windows services*, processes that run in background on the Windows operating system. There are other uses for the term *service* as well. Try not to confuse the different concepts. This article is about *OPC Data Client services*, which are neither OPC UA services nor Windows services nor anything else. In this document, we strive to consistently qualify the term *service* with additional words, wherever needed to avoid ambiguity.

Obtaining Service Interfaces

You can obtain services from a *service provider* object, which is any type that derives, directly or indirectly, from the IServiceProvider interface. The major OPC Data Client components, such as EasyDAClient, EasyAEClient or EasyUAClient, and some other components, are all service providers as well.

The OPC Data Client services are identified by service type, which a .NET Type object, usually an interface. In order to

obtain a service from a service provider, call its GetService method, passing it the type of service of you want to obtain. In most cases, the returned object is of the type you have specified (unless documented otherwise). You would therefore normally cast the received Object to the expected service type. In order to make the coding easier (in .NET), you can use the GetService extension method, which saves you from using the typeof operator (in C#, or its equivalent in other languages) and from casting the result.

When developing on the COM platform, you would have troubles obtaining the .NET Type object to pass into the GetService method. In order to overcome these difficulties, we have provided a GetServiceByName method on each COM interface that represents a service provider. The argument to this method is a string instead. The string represent a fully qualified name of the service type you want to obtain. For example, in order to obtain the _EasyUAClientApplication service from the _EasyUAClient, call is GetServiceByName method, passing it a string **"OpcLabs.EasyOpc.UA.Application.ComTypes._EasyUAClientApplication"**.

The GetService (or GetServiceByName) method returns a null reference when the specified interface type is not available. The set of services may depend on the various factors, such as the client object used, its configuration, software version etc. Unless you are sure that the service is available, your code should be able to handle the null result well, e.g. by gracefully degrading its functionality.

Service Catalog

Different objects provide different types of services. The following paragraphs provide an overview of the types of services available from each major OPC Data Client component.

EasyDAClient Services

The EasyDAClient object can provide following services:

Service Type (.NET)	Service Type (COM)	Title/Purpose	Description
IDisposable	IDisposable	Disposable Object	Provides a mechanism for releasing unmanaged resources. Useful when you deal with a client interface already downcasted to IServiceProvider.
ILicenseInfoProvider	×	License Info Provider	Provides information about the licensed object. Example: **Examples - Licensing - Obtain serial number (Section 13.2.1.1)**.
IEasyDAClient	_EasyDAClient	OPC-DA Client	The client itself. Useful when you deal with a client interface already downcasted to IServiceProvider.
IEasyDAClientSettings	×	OPC-DA Client Settings	Provides access to settings for IEasyDAClient objects.

EasyAEClient Services

The EasyAEClient object can provide following services:

Service Type (.NET)	Service Type (COM)	Title/Purpose	Description
IDisposable	IDisposable	Disposable Object	Provides a mechanism for releasing unmanaged resources. Useful when you deal with a client interface already downcasted to IServiceProvider.
ILicenseInfoProvider	×	License Info Provider	Provides information about the licensed object. Example: **Examples - Licensing - Obtain serial number (Section 13.2.1.1)**.
IEasyAEClient	_EasyAEClient	OPC A&E Client	The client itself. Useful when you deal with a client interface already downcasted to IServiceProvider.
IEasyAEClientSettings	×	OPC A&E Client Settings	Provides access to settings for IEasyAEClient objects.

EasyUAClient Services

The EasyUAClient object can provide following services:

Service Type (.NET)	Service Type (COM)	Title/Purpose	Description
IDisposable	IDisposable	Disposable Object	Provides a mechanism for releasing unmanaged resources. Useful when you deal with a client interface already downcasted to IServiceProvider.
ILicenseInfoProvider	×	License Info Provider	Provides information about the licensed object. Example: **Examples - Licensing - Obtain serial number (Section 13.2.1.1)**.
IEasyUAClientApplication	_EasyUAClientApplication	OPC UA Client Application	Allows management of the **OPC UA Client Application Service (Section 6.3.1)**.
IEasyUAClient	_EasyUAClient	OPC UA Client	The client itself. Useful when you deal with a client interface already downcasted

			to IServiceProvider.
IEasyUAClientSettings	×	OPC UA Client Settings	Provides access to settings for IEasyUAClient objects.
IEasyUAClientComplexData	_EasyUAClientComplexData	OPC UA Complex Data	Gives advanced access to **OPC UA Complex Data Extension (Section 7.2.1)**. Only available if the corresponding plug-in is enabled. For more information, see also **Navigation in the OPC UA data model (Section 7.2.1.4.3)** and **Adding or removing data type dictionaries to or from the OPC UA data type system (Section 7.2.1.4.4)** in **Advanced OPC UA Complex Data Tasks (Section 7.2.1.4)**.

EasyUAAlarmsAndConditionsClient Services

The EasyUAAlarmsAndConditionsClient object can provide following services:

Service Type (.NET)	Service Type (COM)	Title/Purpose	Description
IDisposable	IDisposable	Disposable Object	Provides a mechanism for releasing unmanaged resources. Useful when you deal with a client interface already downcasted to IServiceProvider.
IEasyUAAlarmsAndConditionsClient	_EasyUAAlarmsAndConditionsClient	OPC UA Alarms and Conditions Client	The specialized client itself. Useful when you deal with a client interface already downcasted to IServiceProvider.
ILicenseInfoProvider	×	License Info Provider	Provides information about the licensed object. Example: **Examples - Licensing -**

			Obtain serial number (Section 13.2.1.1).

EasyUACertificateManagementClient Services

The EasyUACertificateManagementClient object can provide following services:

Service Type (.NET)	Service Type (COM)	Title/Purpose	Description
IDisposable	IDisposable	Disposable Object	Provides a mechanism for releasing unmanaged resources. Useful when you deal with a client interface already downcasted to IServiceProvider.
IEasyUACertificateManagementClient	_EasyUACertificateManagementClient	OPC UA Certificate Management Client	The specialized client itself. Useful when you deal with a client interface already downcasted to IServiceProvider.
ILicenseInfoProvider	×	License Info Provider	Provides information about the licensed object. Example: **Examples - Licensing - Obtain serial number (Section 13.2.1.1)**.

EasyUAGlobalDiscoveryClient Services

The EasyUAGlobalDiscoveryClient object can provide following services:

Service Type (.NET)	Service Type (COM)	Title/Purpose	Description
IDisposable	IDisposable	Disposable Object	Provides a mechanism for releasing unmanaged resources. Useful when you deal with

			a client interface already downcasted to IServiceProvider.
IEasyUAGlobalDiscoveryClient	_EasyUAGlobalDiscoveryClient	OPC UA Global Discovery Client	The specialized client itself. Useful when you deal with a client interface already downcasted to IServiceProvider.
ILicenseInfoProvider	×	License Info Provider	Provides information about the licensed object. Example: **Examples - Licensing - Obtain serial number (Section 13.2.1.1)**.

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

6.3.1 OPC UA Client Application Service

This OPC Data Client service allows management of OPC UA client application. The OPC UA Client Application Service has high-level properties and methods for tasks related to maintaining application registrations in the GDS servers, obtaining instance certificate from GDS, refreshing application trust lists from GDS, and similar tasks.

If you can, prefer use of the OPC UA Client Application Service over implementing the same functionality yourself, e.g. with the help of **OPC UA Global Discovery Client (Section 6.4.1)** and/or **OPC UA Certificate Management Client (Section 6.4.2)**. The OPC UA Client Application Service already has all the necessary logic needed to perform the typical client-side application tasks properly and easily.

In This Topic

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

Specifically, methods in this service that work with the Global Discovery Server (GDS) are not licensed for use in lower editions of OPC Data Client.

Exporting

In order to export the registration data of the OPC UA application into an XML file, call the ExportRegisteredApplication Method. This method exports the security settings in the format used by the GDS client from OPC Foundation (Windows desktop sample). It uses the **RegisteredApplication** schema (which is not part of the OPC UA standard).

In order to export the security settings of the OPC UA application into an XML file, call the ExportSecuredApplication Method. This method exports the security settings in the format described in OPC UA Specification Part 6, Annex "Security settings management". The file conforms to the **SecuredApplication** schema.

Managing GDS Registrations

The OPC UA Client Application Service is capable of maintaining client application registrations with one or more GDS servers simultaneously. The methods described further below allow you to control these registrations.

The service keeps track of the registrations (and unregistrations) performed. You can use the ApplicationIdDictionary Property to figure out the application IDs assigned to the current client application by the OPC UA Global Discovery Servers.

> Registration of OPC UA clients in the GDS is not "as important" as registration of OPC UA servers, because (except for so-called Reverse Connect) it is the clients that need to discover the servers, and not vice versa. The application registration is, however, a prerequisite for certificate management (also typically provided by the GDS), and for this reason, you may find yourself dealing with registration of OPC UA client application with the GDS anyway.

Registering to GDS

In order to register the current client application with the OPC UA Global Discovery Server (GDS), call the RegisterToGds Method. This method creates an application registration in the GDS, assigning it a new application ID. Existing registrations with the same application URI are removed first.

The difference between the RegisterToGds and UpdateGdsRegistration methods is that the RegisterToGds Method always obtains a new application ID, whereas the UpdateGdsRegistration Method attempts to reuse the existing application ID, if known. Neither of these methods requires the GDS registration be in any particular state for it to succeed, and both methods assure that after a successful execution, there is one and only one registration in the given GDS for this application.

The identity of the application itself is carried by its application URI, as given by the ApplicationUriString returned by the GetApplicationElement Method. Methods on this interface that manipulate or inspect the GDS registration use the application URI to identify the registration records belonging to this application.

For ane example to this method, see: **Examples - OPC UA Application - Register to GDS (Section 13.2.7.7)**.

Updating GDS Registration

In order to update the registration of the current client application within the OPC UA Global Discovery Server (GDS), call the UpdateGdsRegistration Method. This method updates an application registration in the GDS, keeping its application ID. A new registration is created if the application is not yet registered in the GDS. Preexisting registrations with the same application URI are removed.

The difference between the RegisterToGds and UpdateGdsRegistration methods is that the RegisterToGds Method always obtains a new application ID, whereas the UpdateGdsRegistration Method attempts to reuse the existing application ID, if known. Neither of these methods requires the GDS registration be in any particular state for it to succeed, and both methods assure that after a successful execution, there is one and only one registration in the given GDS for this application.

The identity of the application itself is carried by its application URI, as given by the ApplicationUriString returned by the GetApplicationElement Method. Methods on this interface that manipulate or inspect the GDS registration use the application URI to identify the registration records belonging to this application.

Unregistering from GDS

In order to remove the registration of the current client application from the OPC UA Global DIscovery Server (GDS), call the UnregisterFromGds Method. All existing registrations for the application URI are removed.

This method does not return an error or throw an exception if the application is not currently registered in the GDS.

C#

```
// Shows how to delete an application registration from the GDS.

using System;
using OpcLabs.BaseLib.Extensions;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.Application;
using OpcLabs.EasyOpc.UA.Extensions;
using OpcLabs.EasyOpc.UA.OperationModel;

Finding GDS Registrations

In order to find all registrations for the current client application (using its application URI) in the OPC UA Global Discovery Server (GDS), call the FindGdsRegistrations Method. The method returns a dictionary of UAApplicationElement objects with application registration information, keyed by a UANodeId which is the application ID identifying the registration in the GDS.

The identity of the application itself is carried by its application URI, as given by the ApplicationUriString returned by the GetApplicationElement Method. Methods on this interface that manipulate or inspect the GDS registration use the application URI to identify the registration records belonging to this application.

For ane example to this method, see: **Examples - OPC UA Application - Find all our registrations in GDS (Section 13.2.7.1)**.

Getting Application Element

"Application element" is a data structure that contains registration information about an OPC UA application, i.e. how the application is configured to register itself in OPC UA ecosystem. In order to get the registration information for the current client application, call the GetApplicationElement Method.

The data contained the application element is implementation-dependent. For the OPC UA client application service on the EasyUAClient Class implemented with the OPC Foundation's UA SDK, it is determined by the settings in the UAClientApplicationParameters Class. In order to modify these parameters, access the ApplicationParameters Property of EngineParameters Property of static SharedParameters Property.

For ane example to this method, see: **Examples - OPC UA Application - Get registration information (Section 13.2.7.3)**.

Managing Certificates

Some methods in this group work with the OPC UA Global Discovery Server (GDS) in the role of Certificate Manager (CM). Use of the certificate manager can significantly simplify the management of OPC UA security. Only use these methods if your OPC UA setup includes such Global Discovery Server.

Obtaining a New Certificate

In order to begin an asynchronous operation that obtains a enw application instance certificate from the certificate manager and stores it for subsequent usage, call the BeginObtainNewCertificate Method.

The operation is asynchronous, because it involves multiple steps, and waiting for a finalization of the request by the GDS (see the IEasyUACertificateManagementClient.FinishRequest method). End of the operation is handled by the IEasyUAClientApplication.EndObtainNewCertificate method. The operation can be cancelled using the IEasyUAClientApplication.CancelObtainNewCertificate method.

For a synchronous alternative, see the ObtainNewCertificate Extension Method, with its overloads.

For a task-based asynchronous programming pattern alternative, see the ObtainNewCertificateAsync Extension Method, with its overloads.

Refreshing Trust Lists

In order to retrieve the current trust lists for the application from the certificate manager, and refresh own certificate stores accordingly, call the RefreshTrustLists Method.

The operation first updates the application's registration in the GDS, before retrieving the trust lists from the certificate manager and adding them to the certificate stores

C#

```
// Shows how to refresh own certificate stores using current trust lists for the
application from the certificate manager.

Getting Instance Certificate

In order to get the instance certificate the application is currently configured to use, call the GetInstanceCertificate Method.

The method returns the instance certificate, if found. It returns null if the instance certificate cannot be found.

Getting Certificate Subject Name

In order to get the the subject distinguished name the application is configured to use for its certificates, call the GetCertificateSubjectName Method.

The value returned is implementation-dependent. For the OPC UA client application service on the EasyUAClient Class implemented with the OPC Foundation's UA SDK, it is determined by the settings in the UAClientApplicationParameters Class, as described here: **Providing OPC UA Client Instance Certificate (Section 4.13.1.1)**,

For ane example to this method, see: **Examples - OPC UA Application - Get certificate subject name (Section 13.2.7.2)** .

6.4 Specialized Client Objects

A specialized client object builds on top of a general-purpose client object (such as EasyUAClient) and provides functionality that is relevant for specific problem domain. It contains, in a sense, pre-packaged pieces of reusable code that the developer would typically need to write, whenever he needs to develop a solution for that problem domain.

In OPC UA, the problem domain addressed by the specialized client object is often a selected part of the OPC UA specification. This is due to the layered architecture of OPC UA, where additional informational models can be used to enhance the functionality and address new problem domains, while the basic set of services (covered by the general-purpose client object) remains static and relatively small.

In This Topic

Specialized Client Derivation

A specialized client object can be created from an existing general-purpose client (such as when you have the IEasyUAClient Interface) using so-called *derivation*. For derivation, there is a method (or an extension method) on the general-purpose client, that returns the specialized client needed. For example, you can call the AsGlobalDiscoveryClient (Extension) Method on the IEasyUAClient Interface, and you will receive back a specialized client object for OPC UA global discovery.

A specialized client object created using derivation performs its operations using the general-purpose client object that it was derived from, and therefore also uses all its settings, always shares the same connections, etc. You can then think of the specialized client simply as a functionality extension of the general-purpose client object.

It is recommended that you use the specialized client derivation whenever you have a suitable general-purpose client object available.

Standalone Specialized Clients

A specialized client object can also be created standalone, without having a general-purpose client object first. This is done simply by instantiating the specialized client object, e.g. EasyUAGlobalDiscoveryClient. When created in this way, the specialized client object will use an internal general-purpose client to perform its operations. The parameters of such general-purpose client object, if they are of interest to you, are available in the ClientSelector Property of the specialized client. Note that if you want to change any of these parameters, you must do so before you perform the first operation on the specialized client object. Also note that the internal general-purpose client object may be used for multiple purposes by OPC Data Client.

The example below uses a standalone specialized client object to perform OPC UA global discovery operation.

            For Each applicationId As UANodeId In clientApplicationIds
                Console.WriteLine()
                Console.WriteLine("Application ID: {0}", applicationId)

                Try
                    globalDiscoveryClient.UnregisterApplication(gdsEndpointDescriptor,
applicationId)
                Catch uaException As UAException
                    Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException.Message)
                    Continue For
                End Try
                Console.WriteLine("Unregistered.")
            Next applicationId
        End Sub
    End Class
End Namespace
```

Visual Studio Toolbox

The standalone specialized clients are also available as icons in the Visual Studio Toolbox. This means that in certain types of projects, they can be dragged from the Toolbox to the design surface, and Visual Studio will create code to instantiate and configure the specialized client object. Component properties are then also editable from the Visual Studio (in the Properties tool window).

Reverting to the General-Purpose Client Object

In a similar as you can derive a specialized client object from a general-purpose client, you can go in the opposite direction. If you have a specialized client object at hand, you can use its AsClient method to obtain the client object upon which the specialized client is built. If the specialized client object has been derived from a general-purpose client, this method returns the original general-purpose client object used in derivation. If the specialized client object us standalone, this method returns the internal general-purpose client object used by this specialized client.

The IsDerived Property determines whether a given specialized client object has been derived from a general-purpose client object.

Specialized Clients Catalog

There are currently following specialized client objects available:

- OPC UA Alarms and Conditions Client. See **Modifying Information (OPC UA Alarms & Conditions) (Section 5.1.4.2)** under **Imperative Programming Model for OPC UA Alarms & Conditions (Section 5.1.4)**.
- **OPC UA Global Discovery Client (Section 6.4.1)**. Provides access to information model of an OPC UA Global Discovery Server (GDS).
- **OPC UA Certificate Management Client (Section 6.4.2)**. Provides access to certificate management (CM) information model of an OPC UA Global Discovery Server (GDS).
- **OPC UA Publish-Subscribe Client (Section 6.4.3)**. Provides access to information model in OPC UA PubSub.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

6.4.1 OPC UA Global Discovery Client

In This Topic

Example

The OPC UA Global Discovery Client is a specialized OPC UA client object for global discovery. In the OPC UA specifications, the functionality covered by this type is described in Part 12: Discovery and Global Services, in the Global Discovery Server section.

This specialized client object can be derived from IEasyUAClient Interface using the AsGlobalDiscoveryClient Extension Method, or it can be created standalone as EasyUAGlobalDiscoveryClient Component.

This interface contains methods to communicate with the OPC UA Global Discovery Server (GDS) using its information model for global discovery, making the work of assembling the proper OPC UA method parameters and retrieving the results. The methods allow querying for applications and/or servers, and registering, unregistering or updating application registrations in the GDS. Only the global discovery aspect of the GDS information is covered by this interface. Certificate management (CM), key credential management, and authorization services are treated separately.

> ⚠ Before deciding to use methods provided by this specialized client, it is recommended that you have a look at the IEasyUAClientApplication service (see **OPC UA Client Application Service (Section 6.3.1)**), available from IServiceProvider.GetService method from the IEasyUAClient interface. The client application service works on higher level, and conveniently combines several methods together to achieve the typically needed functionality related to GDS and certificate management in OPC UA.

Available methods are:

- FindApplications Method. Finds the application records for an OPC UA application known to the GDS.
- GetApplication Method. Gets a specific application record for an OPC UA application known to GDS.
- QueryApplications Method. Finds client or server applications that meet the specified filters.
- QueryServers Method. (Depreciated) Finds server applications that meet the specified filters.
- RegisterApplication Method. Registers a new application instance with a Global Directory Server.
- UnregisterApplication Method. Removes an application from a Global Discovery Server.
- UpdateApplication Method. Updates an existing application in a Global Discovery Server.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

6.4.2 OPC UA Certificate Management Client

The OPC UA Certificate Management Client is a specialized OPC UA client object providing access to certificate management (CM) information model of an OPC UA Global Discovery Server (GDS). In the OPC UA specifications, the functionality covered by this type is described in Part 12: Discovery and Global Services, in the section Certificate Management Overview.

This specialized client object can be derived from IEasyUAClient Interface using the AsCertificateManagementClient Extension Method, or it can be created standalone as EasyUACertificateManagementClient Component.

This interface contains methods to communicate with the OPC UA Global Discovery Server (GDS) using its information model for certificate management, making the work of assembling the proper OPC UA method parameters and retrieving the results. The methods allow getting certificate groups, requesting key pairs or certificate signing and obtaining the results, retrieving trust lists, and more.

> ⚠ Before deciding to use methods provided by this specialized client, it is recommended that you have a look at the IEasyUAClientApplication service (see **OPC UA Client Application Service (Section 6.3.1)**), available from IServiceProvider.GetService method from the IEasyUAClient interface. The client application service works on higher level, and conveniently combines several methods together to achieve the typically needed functionality related to GDS and certificate management in OPC UA.

Available methods are:

- FinishRequest Method. Finishes a certificate request started with a call to StartNewKeyPairRequest Method or StartSigningRequest Method.
- GetCertificateGroups Method. Returns the certificate groups assigned to application.
- GetCertificateStatus Method. Checks if an application needs to update its certificate.
- GetTrustList Method. Retrieves the node ID of a trust list assigned to an application.
- StartNewKeyPairRequest Method. Starts a request for a new certificate and private key. The certificate and private key are returned in the FinishRequest response.
- StartSigningRequest Method. Initiates a request to create a certificate which uses the private key which the caller currently has. The new certificate is returned in the FinishRequest response.

6.4.3 OPC UA Publish-Subscribe Client

Introduction

In This Topic

The OPC UA Publish-Subscribe Client is a specialized client object providing access to PubSub information model in OPC UA.

Note that although the OPC UA PubSub exchanges the data using its own protocols and can stay on its own, the information model provides additional useful integration with OPC UA infrastructure. The information model for OPC UA PubSub is accessed using "normal" OPC UA Client-Server technologies. This means that the OPC UA Publish-Subscribe Client accesses data in some "live" OPC UA server that must be available at the time your program makes the operations. Additionally, the OPC UA Publish-Subscribe Client gives you access to OPC UA PubSub configuration data stored in files.

This specialized client object can be derived from IEasyUAClient Interface using the AsPublishSubscribeClient Extension Method, or it can be created standalone as EasyUAPublishSubscribeClient Component.

> ⚠ The EasyUAPublishSubscribeClient Class class does **not** have OPC UA Subscriber functionality; if you need that, see EasyUASubscriber Class instead.

> 💡 If your intent is to use the PubSub configuration stored in the OPC UA information model to find data that would allow you to set up a PubSub subscription, you can use the built-in **OPC UA PubSub logical resolution (Section 5.1.5.1.4)** mechanism instead. This will save you lots of work.

> Currently, the OPC UA Publish-Subscribe Client only provides a read-only view of the information model. That is, you cannot use it to change anything. In addition, only the parts relevant to **OPC UA PubSub logical resolution (Section 5.1.5.1.4)** are available (this means that the parts related to reader group and dataset reader configuration are left out).

Functionality

In order to access the PublishSubscribe element, which is at the top of the PubSub information model, use the GetPublishSubscribeElement Method. The PublishSubscribe element allows you to find out which transport profiles are supported by the publisher or subscriber associated with the server, using the SupportedTransportProfileUriStringSet Property.

The HasConfigurationModel Method determines whether the specified OPC UA server provides a PubSub configuration model. This allows you to make such test cleanly, without possibly causing an error (exception being thrown).

The "main" method of the OPC UA Publish-Subscribe client is the AccessReadOnlyConfiguration Method returns the IUAReadOnlyPubSubConfiguration Interface which provides read-only access to PubSub configuration provided by the specified server. If, instead of accessing the "live" configuration in the OPC server, you want to load the PubSub configuration from a specified file (in UABinary format), use the LoadReadOnlyConfiguration Method. The PubSub configuration interface then provides members described in **Accessing OPC UA PubSub Configuration Model (Section 5.1.5.2)**.

If your PubSub configuration is in the UABinary format, but not stored in a file, you can use

the UABinaryReadOnlyConfigurationLoader Property. It returns an instance of StreamLoader Class which you can use to load the configuration from an array of bytes, a Stream, a managed resource, and so on.

For more functionality, and detailed information, see the Reference: IEasyUAPublishSubscribeClient Interface, EasyUAPublishSubscribeClient Class and IEasyUAPublishSubscribeClientExtension Class.

Advanced: Loading PubSub configuration from a file node

Some OPC UA servers offer the PubSub configuration in form of a node representing the OPC UA file object. The file contains the PubSub configuration in the UABinary file, same as it would appear in a regular file (file on disk). This can be the only way the OPC UA server offers the PubSub configuration (possibly because the server is a small embedded server), or it can be in addition to the standard way of providing the PubSub configuration (which involves many related OPC UA nodes in a complex mesh). Representing the PubSub configuration is for many uses cases practical, but nevertheless non-standard practice. It appears mainly in servers built with Unified Automation toolkit(s).

OPC Data Client has ability to load such PubSub configuration and work with it. If you know that the PubSub configuration is stored in this way in the server, you can use the LoadReadOnlyConfigurationFromFileNode Method to load it. There is also the HasConfigurationFileNode Method to test whether the "well-known" node with PubSub configuration is present in the server.

For generic case (when you do not know how the PubSub configuration is stored in the server), we recommend using the AccessOrLoadReadOnlyConfiguration Method. This method can decide dynamically, based on the actual OPC UA server contents, which approach to use to provide the PubSub configuration interface to you. Note the possible differences in behavior between the PubSub configuration interfaces returned in each case, described further in this article.

Differences between "live" and loaded PubSub configurations

Accessing a PubSub configuration that is "live" in the OPC UA server always gives you the current status of the configuration, at every moment you call some operation on the PubSub configuration interface. This may be a good thing (if you are interested in up-to-date state), but also a bad thing (because OPC UA does not provide transactional access to the PubSub configuration, the information may change while you are working with different parts of it, and your code needs to be able to deal with it). Accessing a "live" PubSub configuration is generally slow (each operation requires one or more OPC UA service calls), and it may fail at any time (any operation may return an error caused by inability to perform the intended OPC UA service on the server).

In contrast, when you load the PubSub configuration from a file (or OPC UA file node in the server), it represents a one-time snapshot that does not change by itself. It resides in memory, and accessing it is fast. If used correctly, it also generally does not return any errors.

Examples

For easy set up, the examples provided here access OPC UA PubSub configuration data stored in a pre-made binary configuration file. The same principle can, however, be used to access configuration data provided by an OPC server. There are commented statements in the examples that show how to do it.

The example below starts at the "root" of the PubSub configuration, and first obtains names of all PubSub connections available (they are at the 1st level). For each PubSub connection, given its name, it obtains names of writer groups configured on that PubSub connection (they are at the 2nd level). And, for each such writer group, given its name, it obtains names of all dataset writers configured on that writer group (they are at the 3rd level). Besides the PubSub object names, the commented parts also show how to obtain more detailed information about each PubSub object.

C#

```
// This example obtains and prints out information about PubSub connections, writer
groups, and dataset writers in the
// OPC UA PubSub configuration.

using System;
using OpcLabs.BaseLib.Collections.Specialized;
using OpcLabs.EasyOpc.UA.OperationModel;

```

The example below uses the ListAllPublishedDataSetNames Method to retrieve all published dataset from the PubSub configuration. The published datasets are actually organized in the PubSub configuration using a hierarchical structure of dataset folders. The word "all" in the method name denotes that the method will truly return all published datasets in the configuration, not just those at the "root" of the dataset folder structure, or in any specified dataset folder. The method will act recursively in the dataset folder structure, if needed. There are also methods that allow you to work with contents of individual dataset folders. Note that the published dataset names are unique across the PubSub configuration as a whole (regardless of their location in the dataset folder structure), and therefore a published dataset name is sufficient to identify the published dataset, and the dataset folder path is not strictly necessary.

    ' Get the names of PubSub connections in the configuration, regardless of the
folder they reside in.
    Dim PublishedDataSetNames: Set PublishedDataSetNames =
PubSubConfiguration.ListAllPublishedDataSetNames

    Dim publishedDataSetName: For Each publishedDataSetName In PublishedDataSetNames
        WScript.Echo "Published dataset: " & publishedDataSetName

        ' You can use the statement below to obtain parameters of the published
dataset.
        'Dim PublishedDataSetElement: Set PublishedDataSetElement =
PubSubConfiguration.GetPublishedDataSetElement(Nothing, publishedDataSetName)
    Next
End Sub

' Example output:
'
'Loading the configuration...
'Published dataset: Simple
'Published dataset: AllTypes
'Published dataset: MassTest
'Published dataset: AllTypes-Dynamic
'Finished.
```

⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

7 Extensions

7.1 Layered Extensions for .NET

EasyOPC Extensions for .NET is a pack of .NET classes that adds more functionality to the EasyOPC.NET and EasyOPC-UAcomponents. It is built upon and relies on EasyOPC.NET and EasyOPC-UA, so in fact you could build all these extensions yourself, but it is meant to provide a ready-made, verified code for useful “shortcut” methods to achieve common tasks.

Technically, **Specialized Client Objects (Section 6.4)** are also similar to layered extensions.

7.1.1 Usage

A significant part of the EasyOPC Extensions for .NET functionality is provided in form of so-called Extension Methods. In languages that support them (including C#, VB.NET), extension methods will appear as additional methods on the classes that are being extended. For example, the EasyDAClient class appears as having many more new methods that you can choose from. This way, you can write a code that call e.g. GetDataTypePropertyValue (extension) method on the EasyDAClient object, although the method is actually located in the IEasyDAClientExtension2 class which you do not even have to be aware of.

In languages that do not support extension method syntax, it is still possible to use them, but they need to be called as static method on the extension class, and you provide the object reference as an additional argument. In the above example, you would call IEasyDAClientExtension2**.**GetDataTypePropertyValue instead, and pass it the EasyDAClient object as the first argument.

7.1.1.1 Generic Types

Some methods (described further below) that provide generic access return values (or arrays of values) of type ValueResult<T>. ValueResult<T> is a type derived from ValueResult that holds returns with values of type T. Attempt to store a value of incompatible type causes an exception. This means that you specify the type of the value you expect from OPC, and safely assume that the value of given type will be returned.

Further generic types exist for various OPC specifications. See e.g. Generic Types for OPC Data Access.

7.1.2 OPC Data Access Extensions

This chapter describes EasyOPC.NET extensions for OPC Data Access and OPC XML-DA.

7.1.2.1 Generic Types for OPC-DA

Following generic types are available for use with OPC Data Access and OPC XML-DA:

- DAVtq<T>: Holds typed data value (of type T), timestamp, and quality.
- DAVtqResult<T>: Holds result of an operation in form of a typed DAVtq<T> (value, timestamp, quality).
- DAItemValueArguments<T>: Arguments for an operation on an OPC item. Carries a value of type T.
- DAItemVtqArguments<T>: Arguments for an operation on an OPC item. Carries a DAVtq<T> object.

- EasyDAItemSubscriptionArguments<T>: Arguments for subscribing to an OPC item of type T.
- EasyDAItemChangedEventArgs<T>: Data of an event or callback for a significant change in OPC item of type T.

These types are used with generic access extensions for OPC items (see Generic Access) and with generic access extensions for OPC properties (see Generic Access). They are also use with the Live Mapping Model.

For example, you can call the EasyDAClient.ReadItem<T> extension method with a given type T, and receive back a DAVtq<T> object with a TypedValue already properly typed as T.

Noted that if the untyped property on the base (non-generic) type has a name like **XXXX**, the corresponding typed property on the generic type has a name like TypedXXXX. For example, for an untyped property DAVtqResult.Vtq, there is a corresponding typed property DAVtqResult<T>.TypedVtq.

7.1.2.2 Extensions for OPC Items

7.1.2.2.1 Type-safe Access

With EasyOPC.NET Extensions, you can use type-safe methods that allow reading an item value already converted to the specified type, with methods such as EasyDAClient.ReadItemValueInt32. There is such a method for each primitive type, named ReadItemValueXXXX, where **XXXX** is the name of the type. Using these methods allows your code be free of unnecessary conversions. The methods also take care of passing a proper requested data type to the OPC server.

A corresponding set of methods also exists for one-dimensional arrays of primitive types. Such methods are named ReadItemValueArrayOfXXXX, where **XXXX** is the name of the element type. For example, EasyDAClient.ReadItemValueArrayOfInt32 will read from an item as an array of 32-bit signed integers.

You can also use type-safe methods that allow writing an item value of a specified type, with methods such as EasyDAClient.WriteItemValueInt32. There is such a method for each primitive type, named WriteItemValueXXXX, where **XXXX** is the name of the type. Using these methods allows your code be free of unnecessary conversions. The methods also take care of passing a proper requested data type to the OPC server.

A corresponding set of methods also exists for one-dimensional arrays of primitive types. Such methods are named WriteItemValueArrayOfXXXX, where **XXXX** is the name of the element type. For example, EasyDAClient.WriteItemValueArrayOfInt32 will write into an item as an array of 32-bit signed integers.

7.1.2.2.2 Generic Access

The EasyDAClient.ReadItem<T> extension method reads an OPC item of a given type T, and return the result as DAVtq<T> (typed value/timestamp/quality) object.

The EasyDAClient.ReadItemValue<T> extension method reads an OPC item of a given type T, and return the actual item's value typed as T.

The EasyDAClient.WriteItem<T> extension method writes a typed value/timestamp/quality into an OPC item, using DAVtq<T> object.

The EasyDAClient.WriteItemValue<T> extension method writes a typed value of type T into an OPC item.

There are several overloads of all the above described methods, with different structure of arguments.

7.1.2.3 Extensions for OPC Properties

7.1.2.3.1 Type-safe Access

With EasyOPC.NET Extensions, you can use type-safe methods that allow obtaining a value of an OPC property value already converted to the specified type, with methods such as EasyDAClient.GetPropertyValueInt32. There is such a method for each primitive type, named GetPropertyValueXXXX, where **XXXX** is the name of the type. Using these methods allows your code be free of unnecessary conversions.

A corresponding set of methods also exists for one-dimensional arrays of primitive types. Such methods are named GetPropertyValueArrayOfXXXX, where **XXXX** is the name of the element type. For example, EasyDAClient.GetPropertyValueArrayOfString will obtain a value of a property as an array of strings.

7.1.2.3.2 Generic Access

The EasyDAClient.GetPropertyValue<T> extension method gets a value of OPC property of a given type T, and return the actual value typed as T. There are several overloads of this method with different structure of arguments.

7.1.2.3.3 Well-known Properties

A common scenario is to work with well-known OPC properties. With EasyOPC.NET Extensions, you can quickly obtain a value of any well-known OPC property of a given OPC item, with methods such as EasyDAClient.GetDataTypePropertyValue. All these methods are named GetXXXXPropertyValue, where **XXXX** is the name of the property. The methods also check the value type and convert it to the type that corresponds to the property. For example, GetDataTypePropertyValue method returns a VarType, GetScanRatePropertyValue method returns a float, and GetDescriptionPropertyValue method returns a string.

C#

```
// This example shows how to obtain a data type of an OPC item.

using System;
using OpcLabs.BaseLib.ComInterop;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.Extensions;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClientExtension
{
    class GetDataTypePropertyValue
    {
        public static void Main1()
        {
            var client = new EasyDAClient();

            // Get the DataType property value, already converted to VarType
            VarType varType;
            try
            {
                varType = client.GetDataTypePropertyValue("", "OPCLabs.KitServer.2",
"Simulation.Random");
            }
```

```
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }

            // Display the obtained data type
            Console.WriteLine("VarType: {0}", varType); // Display data type
symbolically
        }
    }
}
```

VB.NET

```
' This example shows how to obtain a data type of an OPC item.

Imports OpcLabs.BaseLib.ComInterop
Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.DataAccess.Extensions
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess._EasyDAClientExtension
    Friend Class GetDataTypePropertyValue
        Public Shared Sub Main1()
            Dim client = New EasyDAClient()

            ' Get the DataType property value, already converted to VarType
            Dim varType As VarType
            Try
                varType = client.GetDataTypePropertyValue("", "OPCLabs.KitServer.2",
"Simulation.Random")
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message)
                Exit Sub
            End Try

            ' Display the obtained data type
            Console.WriteLine("VarType: {0}", varType) ' Display data type symbolically
        End Sub
    End Class
End Namespace
```

7.1.2.3.4 Alternate Access Methods

The GetPropertyValueDictionary method allows you to obtain a dictionary of property values for a given OPC item, where a key to the dictionary is the property Id. You can pass in a set of property Ids that you are interested in, or have the method obtain all well-known OPC properties. You can then easily extract the value of any property by looking it up in a dictionary (as opposed to having to numerically index into an array, as with the base GetMultiplePropertyValues method).

C#

```
// This example shows how to obtain a dictionary of OPC property values for an OPC
item, and extract property values.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.Extensions;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClientExtension
{
    class GetPropertyValueDictionary
    {
        public static void Main1()
        {
            var client = new EasyDAClient();

            // Get dictionary of property values, for all well-known properties
            DAPropertyValueDictionary propertyValueDictionary;
            try
            {
                propertyValueDictionary = client.GetPropertyValueDictionary("",
"OPCLabs.KitServer.2", "Simulation.Random");
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }

            // Display some of the obtained property values
            // The production code should also check for the .Exception first, before
getting .Value

Console.WriteLine("propertyValueDictionary[DAPropertyId.AccessRights].Value: {0}",
                propertyValueDictionary[DAPropertyIds.AccessRights].Value);
            Console.WriteLine("propertyValueDictionary[DAPropertyId.DataType].Value:
{0}",
                propertyValueDictionary[DAPropertyIds.DataType].Value);
            Console.WriteLine("propertyValueDictionary[DAPropertyId.Timestamp].Value:
{0}",
                propertyValueDictionary[DAPropertyIds.Timestamp].Value);
        }
    }
}
```

VB.NET

```
' This example shows how to obtain a dictionary of OPC property values for an OPC item,
and extract property values.

Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.DataAccess.Extensions
Imports OpcLabs.EasyOpc.OperationModel
```

```
Namespace DocExamples.DataAccess._EasyDAClientExtension
    Friend Class GetPropertyValueDictionary
        Public Shared Sub Main1()
            Dim client = New EasyDAClient()

            ' Get dictionary of property values, for all well-known properties
            Dim propertyValueDictionary As DAPropertyValueDictionary
            Try
                propertyValueDictionary = client.GetPropertyValueDictionary("",
"OPCLabs.KitServer.2", "Simulation.Random")
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message)
                Exit Sub
            End Try

            ' Display some of the obtained property values
            ' The production code should also check for the .Exception first, before
getting .Value

Console.WriteLine("propertyValueDictionary[DAPropertyId.AccessRights].Value: {0}",
propertyValueDictionary(DAPropertyIds.AccessRights).Value)
            Console.WriteLine("propertyValueDictionary[DAPropertyId.DataType].Value:
{0}", propertyValueDictionary(DAPropertyIds.DataType).Value)
            Console.WriteLine("propertyValueDictionary[DAPropertyId.Timestamp].Value:
{0}", propertyValueDictionary(DAPropertyIds.Timestamp).Value)
        End Sub
    End Class
End Namespace
```

The GetItemPropertyRecord method allows you to obtain a structure filled in with property values for a given OPC item. It can retrieve all well-known properties at once, or you can pass in a set of property Ids that you are interested in. You can then simply use the properties in the resulting DAItemPropertyRecord structure, without further looking up the values in any way.

C#

```
// This example shows how to obtain a structure containing property values for an OPC
item, and display some property values.

using System;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.Extensions;
using OpcLabs.EasyOpc.OperationModel;

namespace DocExamples.DataAccess._EasyDAClientExtension
{
    class GetItemPropertyRecord
    {
        public static void Main1()
        {
            var client = new EasyDAClient();
```

```
            // Get a structure containing values of all well-known properties
            DAItemPropertyRecord itemPropertyRecord;
            try
            {
                itemPropertyRecord = client.GetItemPropertyRecord("",
"OPCLabs.KitServer.2", "Simulation.Random");
            }
            catch (OpcException opcException)
            {
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message);
                return;
            }

            // Display some of the obtained property values
            Console.WriteLine("itemPropertyRecord.AccessRights: {0}",
itemPropertyRecord.AccessRights);
            Console.WriteLine("itemPropertyRecord.DataType: {0}",
itemPropertyRecord.DataType);
            Console.WriteLine("itemPropertyRecord.Timestamp: {0}",
itemPropertyRecord.Timestamp);
        }
    }
}
```

VB.NET

```
' This example shows how to obtain a structure containing property values for an OPC
item, and display some property values.

Imports OpcLabs.EasyOpc.DataAccess
Imports OpcLabs.EasyOpc.DataAccess.Extensions
Imports OpcLabs.EasyOpc.OperationModel

Namespace DocExamples.DataAccess._EasyDAClientExtension
    Friend Class GetItemPropertyRecord
        Public Shared Sub Main1()
            Dim client = New EasyDAClient()

            ' Get a structure containing values of all well-known properties
            Dim itemPropertyRecord As DAItemPropertyRecord
            Try
                itemPropertyRecord = client.GetItemPropertyRecord("",
"OPCLabs.KitServer.2", "Simulation.Random")
            Catch opcException As OpcException
                Console.WriteLine("*** Failure: {0}",
opcException.GetBaseException().Message)
                Exit Sub
            End Try

            ' Display some of the obtained property values
            Console.WriteLine("itemPropertyRecord.AccessRights: {0}",
itemPropertyRecord.AccessRights)
            Console.WriteLine("itemPropertyRecord.DataType: {0}",
itemPropertyRecord.DataType)
            Console.WriteLine("itemPropertyRecord.Timestamp: {0}",
```

```
itemPropertyRecord.Timestamp)
        End Sub
    End Class
End Namespace
```

The static DAPropertyIDSet class gives you an easy way to provide pre-defined sets of properties to the above methods. There are well-known sets such as the Basic property set, Extension set, or Alarms and Events property set. It also allows you to combine the property sets together (a union operation), with the Add method or the '+' operator.

7.1.3 OPC Alarms&Events Extensions

This chapter describes EasyOPC.NET extensions for OPC Alarms&Events.

> This functionality is not available under (or the text does not apply to) .NET Standard development platform.

7.1.3.1 OPC-A&E Queries

The extension method EasyAEClient.FindEventCategory attempts to find an event category given by its numerical category ID in the OPC server. If successful, it provides the AECategoryElement filled in with details about the event category.

The extension method EasyAEClient.FindEventCondition attempts to find an event condition in the OPC server, given the numerical category ID, and event condition name. If successful, it provides the AEConditionElement filled in with details about the event condition.

7.1.4 OPC Unified Architecture Extensions

This chapter describes EasyOPC extensions for OPC Unified Architecture (OPC-UA).

7.1.4.1 Extensions on Helper Types

The UAApplicationTypes.IsServer extension method allows you to determine whether a UA application (as returned e.g. by server discovery) includes OPC-UA server functionality. This is a shortcut for testing whether the application type is either Server or ClientOrServer.

The extensions on the UANodeElement (as returned e.g. by browsing for OPC-UA nodes) allow finer categorization of the nodes over what is provided just by the NodeClass property. For example, you can test whether a node is a Data Variable or a Property, by extensions methods IsDataVariable and IsProperty.

7.1.4.2 Extensions for OPC UA reading

The ReadDataType Method reads a value of DataType attribute of a node.

The ReadMultipleDataTypes Method reads value of DataType attribute of multiple nodes, using array of argument objects

as an input.

7.2 Integrated Extensions

Integrated extensions are extensions whose fuctions resides inside the objects you use. That is, they modify or extend the behavior of existing objects. The advantage of such approach is that the new functionality can be added transparently, and the code that uses them does have (in many cases) be aware of their existence or look any different.

7.2.1 OPC UA Complex Data Extension

In OPC UA, servers can stick to the standard types defined in the OPC UA specifications, or they can define their own types. The "non-standard" data types can be completely server-specific, or can conform to some industry standard. Usage of these data types is commonly referred to as *OPC UA complex data*. With complex data, it is possible that the data type is not even know at compile time; instead, it can be discovered, constructed or processed during runtime, without prior knowledge of it.

Use of OPC UA complex data poses a new range of interoperability problems. When the server uses some new data type, how can the client know what the data type is, and how is the data encoded? The data is basically a binary blob that is transferred as a block between the server and the client, and who knows what it means? In some cases, the client can be hard-coded with upfront knowledge of what this binary blob of data (called *extension object*) contains and how it is encoded. But that is only when the client can be written with specific knowledge about the server it connects to, and even then decoding of the data might be a tedious programming task. Thankfully, OPC UA specifications provide ways for servers to describe the data types and their encoding to the clients, using information that can reside in the server itself. This is done

- using so-called *data type dictionaries*, and
- in OPC UA version 1.04 and later also using so-called *data type definitions*.

Knowledge Base: Comparison of OPC UA complex data models .

In OPC Data Client, both models work together and in a unified way from developer's perspective. OPC client can then extract the data type descriptions from these dictionaries or definitions, and be written in a generic way that adjusts to the data types that exist in the server.

Retrieving the associated metadata from the server's information model, interpreting the data type dictionaries or data type definitions, and decoding and encoding data according to data type descriptions is quite complicated. OPC Data Client can do it for you, with the help of the OPC UA Complex Data extension, described in this chapter. With the OPC UA Complex Data extension, you do not have to deal with binary blobs; instead, you work with meaningful structures that represent the data types and the data itself logically.

> ⚠ The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

The OPC UA Complex Data extension integrates into the EasyUAClient Class pipeline, and its functionality is thus transparently available both to .NET and COM programming languages and tools.

7.2.1.1 Basic OPC UA Complex Data operations

The OPC UA Complex Data extension does not require you to perform OPC operations any differently when complex data is involved. You use the same objects and methods as with the regular data. The only difference is in the data that is being passed to or from the component. When the OPC UA Complex Data extension is enabled (which is by default), complex data returned to you by the methods on the EasyUAClient Class is represented by instances of the UAGenericObject Class, and conversely, if you want to pass complex data to some method on the EasyUAClient Class, you need to prepare an instance of UAGenericObject Class.

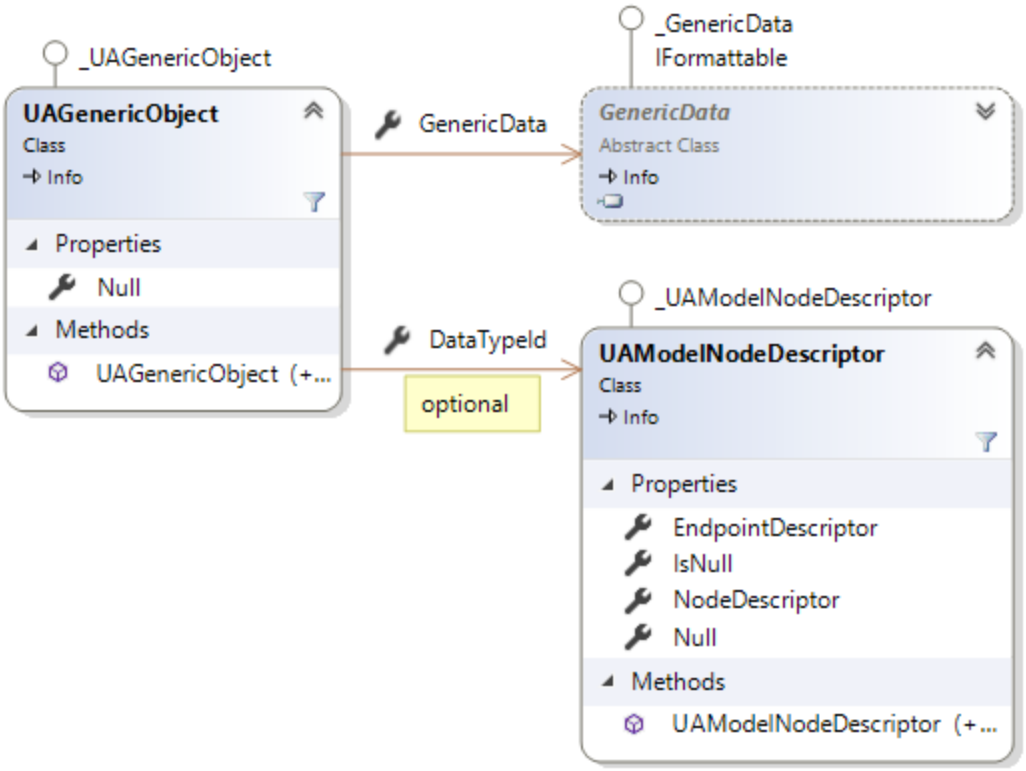
In This Topic

If the node being read, written or subscribed to represents an array (one- or multi-dimensional), the value passed to or from the component is then an array of UAGenericObject-s. Note that this is different from having a scalar node, and a UAGenericObject with generic data in that itself is an array (a sequence data). Both these options are possible (and sometimes a bit confusing).

The UAGenericObject class

The UAGenericObject Class is used to represent complex data on its way from the server or to the server. It has two basic pieces of information:

- The generic data itself, in the GenericData Property. This can be, for example, a primitive type (such as an integer), or a sequence (array), or a structured type with several fields of various types. The OPC UA Complex Data extension gives you methods to process generic data, and to create it. For more information, see **Generic data and data types (Section 7.2.1.2)**.
- An optional data type ID, in the DataTypeId Property. In most cases you do not need to be concerned about the data type ID. It is filled in when an instance of the UAGenericObject Class is returned from the server by the component. When you are sending generic data to the server through the component, you can usually leave this property unfilled, except in some situations where sub-types are involved. For more information, see **Role of the data type ID (Section 7.2.1.1.4)**.



Steps to use complex data

Here is what you need to do in order to work with OPC UA complex data.

- To read complex data information: Call one of the **Read** methods on the EasyUAClient Class as usual. When complex data is returned by the client, you will receive a value that is of type UAGenericObject Class, and you will process its contents. For more information, see **OPC UA Complex Data reading (Section 7.2.1.1.1)**.
- To subscribe to complex data information: Call one of the **Subscribe** methods on the EasyUAClient Class as usual. When complex data is returned by the client, a DataChangeNotification Event or EventNotification Event will be raised (or a corresponding callback will be made). The value in the event arguments will be of type UAGenericObject Class, and you will process its contents. For more information, see **OPC UA Complex Data subscribing (Section 7.2.1.1.2)**.
- To write a complex data information: Prepare an value of the UAGenericObject Class, and call one of the **Write** methods on the EasyUAClient Class as usual. For more information, see **OPC UA Complex Data writing (Section 7.2.1.1.3)**.

With the OPC UA Complex Data extension, it is also possible to call OPC UA methods that have complex data in their input arguments, or that return complex data in their output arguments. You will use a usual call to one of the **Call** methods on the EasyUAClient Class again.

7.2.1.1.1 OPC UA Complex Data reading

To read complex data information, call one of the **Read** methods on the EasyUAClient Class as usual. When complex data is returned by the client, you will receive a value that is of type UAGenericObject Class, and you will process its contents. The actual generic data is in its GenericData Property.

How precisely you process the received generic data depends on the application. In general, there can be two usage cases:

- Your application knows the type of the data to expect. In this case, you can hard-code this knowledge into the application. For example, if you know that the received data is a structure that has a field called "Temperature". You would type-cast the received data to StructuredData, and from the FieldData collection, you will get an element indexed by a string "Temperature". This can then be an instance of PrimitiveData Class, containing the temperature value in its Value Property. For more information, see **Working with generic data (Section 7.2.1.2.1)**.
- Your application does not know the type of the data to expect. This requires more coding, but is also perfectly doable. You will be accessing the generic data information similarly to the above case, but in a more generic way. The GenericData Class gives you a DataType Property, and the DataType object contained in this property gives you the metadata needed. For more information, see **Working with data types (Section 7.2.1.2.2)**.

The example below shows how to read and display OPC UA complex data.

C#

```
// Shows how to read complex data with OPC UA Complex Data plug-in.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.ComplexData;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.ComplexData._EasyUAClient
{
    class ReadValue
    {
        public static void Main1()
        {
            // Define which server and node we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"
            UANodeDescriptor nodeDescriptor =

7.2.1.1.2 OPC UA Complex Data subscribing

To subscribe to complex data information, call one of the **Subscribe** methods on the EasyUAClient Class as usual. When complex data is returned by the client, a DataChangeNotification Event or EventNotification Event will be raised (or a corresponding callback will be made). The value in the event arguments will be of type UAGenericObject Class, and you will process its contents.

How precisely you process the received generic data depends on the application. In general, there can be two usage cases:

- Your application knows the type of the data to expect. In this case, you can hard-code this knowledge into the application. For example, if you know that the received data is a structure that has a field called "Temperature". You would type-cast the received data to StructuredData, and from the FieldData collection, you will get an element indexed by a string "Temperature". This can then be an instance of PrimitiveData Class, containing the temperature value in its Value Property. For more information, see **Working with generic data (Section 7.2.1.2.1)**.
- Your application does not know the type of the data to expect. This requires more coding, but is also perfectly doable. You will be accessing the generic data information similarly to the above case, but in a more generic way. The GenericData Class gives you a DataType Property, and the DataType object contained in this property gives you the metadata needed. For more information, see **Working with data types (Section 7.2.1.2.2)**.

The example below shows how to subscribe to OPC UA complex data and display the incoming values.

C#

```
// Shows how to subscribe to complex data with OPC UA Complex Data plug-in.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.ComplexData._EasyUAClient
{
```

```
    class SubscribeDataChange
    {
        public static void Main1()
        {
            // Define which server and node we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"
            UANodeDescriptor nodeDescriptor =
                "nsu=http://test.org/UA/Data/;i=10867"; //
[ObjectsFolder]/Data.Dynamic.Scalar.StructureValue

            // Instantiate the client object and hook the event handler.
            var client = new EasyUAClient();
            client.DataChangeNotification += client_DataChangeNotification;

            // Subscribe to a node which returns complex data. This is done in the same
way as regular subscribes - just
            // the data returned is different.
            Console.WriteLine("Subscribing...");
            client.SubscribeDataChange(endpointDescriptor, nodeDescriptor,
samplingInterval:1000);

            Console.WriteLine("Processing data change events for 20 seconds...");
            System.Threading.Thread.Sleep(20 * 1000);

            Console.WriteLine("Unsubscribing...");
            client.UnsubscribeAllMonitoredItems();

            Console.WriteLine("Waiting for 5 seconds...");
            System.Threading.Thread.Sleep(5 * 1000);

            // Unhook the event handler.
            client.DataChangeNotification -= client_DataChangeNotification;

            // Example output:
            //
            //Subscribing...

Complex data is also supported and can also be returned in notifications for OPC UA Alarms&Conditions, i.e. in event arguments of type EasyUAEventNotificationEventArgs, used in the EventNotification Event .

7.2.1.1.3 OPC UA Complex Data writing

To write a complex data information, prepare a value of the UAGenericObject Class, and call one of the **Write** methods on the EasyUAClient Class as usual. In the UAGenericObject:

- Fill in the GenericData Property by the generic data you want to write.
- Optionally, fill in the DataTypeId Property by the data type ID specifying the type of data to be written. In some cases, this information is necessary for the Write to succeed. Refer to **Role of the data type ID (Section 7.2.1.1.4)** for related discussion.

For discussion about creating the generic data, refer to **Creating generic data (Section 7.2.1.2.1.2)**. If the GenericData object you have created has a non-null DataType Property, the generic data will be first validated against this associated data type. For details on the validation process, refer to **Generic data validation (Section 7.2.1.2.1.4)**. The validation is optional, because the presence of the data type in the GenericData object is also optional. If no validation takes place, same errors may be discovered later during the encoding process. The validation has the advantage that it is done upfront, without a need to contact the server at all. It is therefore recommended to use it, if the data type is available somehow (see also "Resolving the data type" in **Navigation in the OPC UA data model (Section 7.2.1.4.3)**).

In some cases, you do not have to provide all data that are part of the data type. For example, it may be possible to omit the value for a field that determines a length of sequence in the same structure. For details, see **Generic data auto-complete (Section 7.2.1.3.1)**.

The example below first reads a structured value from the server, and then manipulates (changes) its elements. The modified value is then written to the server. In this case, the data type ID (and also the data type) can be taken over from

what has been provided by the Read.

C#

```
// Shows how to write complex data with OPC UA Complex Data plug-in.

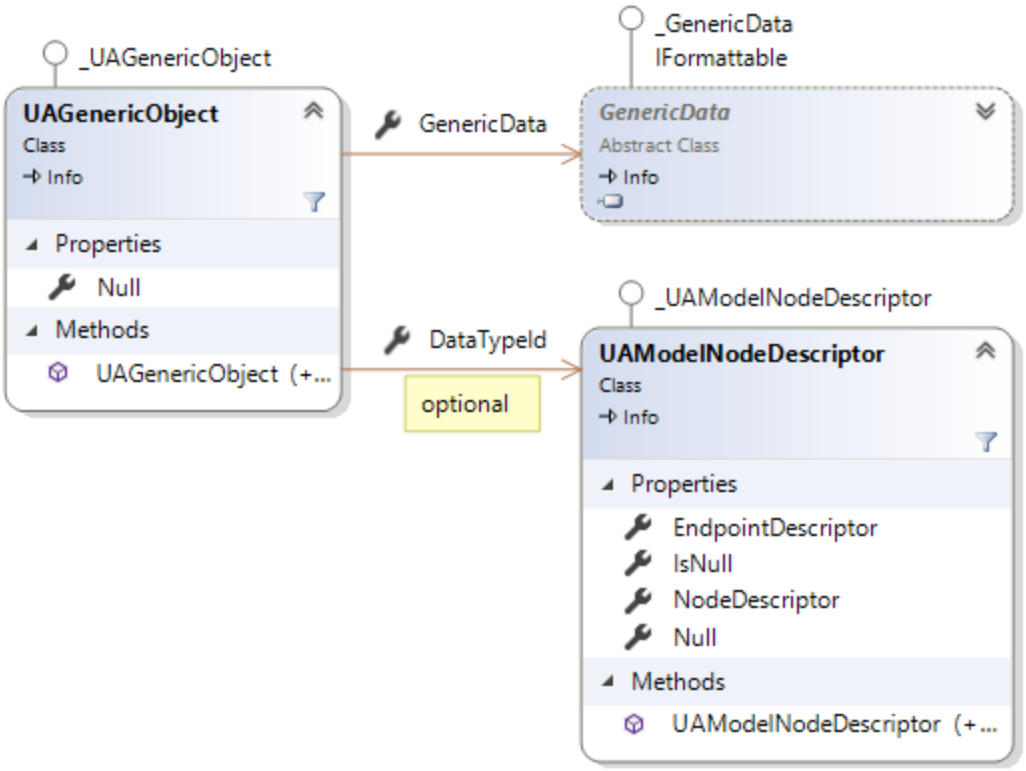
7.2.1.1.4 Role of the data type ID

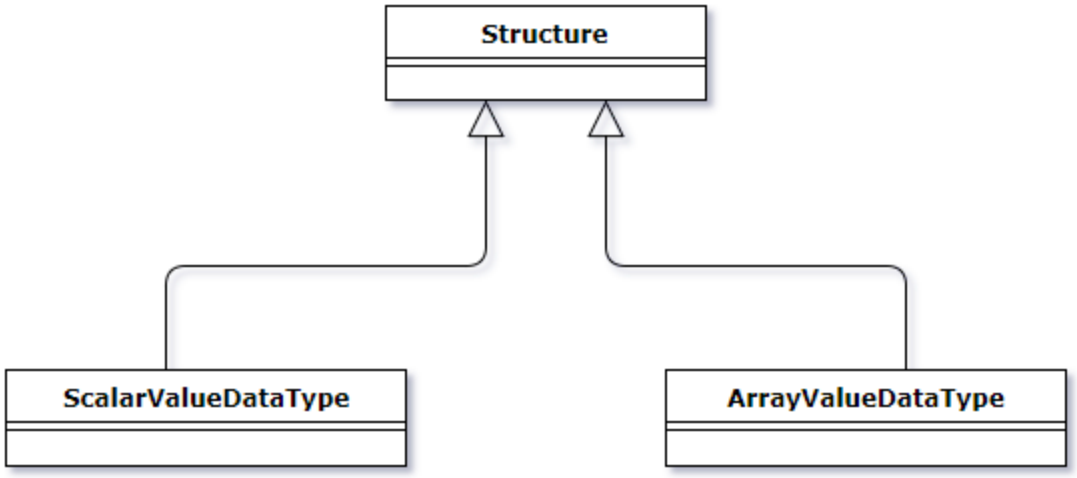
The data type ID (in DataTypeId Property) is an optional information in the UAGenericObject Class (it equals to UAModelNodeDescriptor.Null when "not present"). It is basically a node ID of data type that this UAGenericObject represents.

Show UAGenericObject class diagram



The data type ID of certain node can be determined from the information model of the server (by reading the DataType attribute of that node). That is, however, the **declared** data type for that node. As the OPC UA information model for data types follows the classic paradigms of OOP (Object Oriented Programming), the **actual** data type at runtime can also be any direct or indirect sub-type of the declared data type (in fact, when the declared data type is abstract, the actual data type must be some sub-type, different from the declared type - this is again the same as in classic OOP, because instances of abstract types cannot be created).

In many cases, the node in the OPC UA server you are dealing with has a data type that has no sub-types. In such case, you are lucky, because you always know upfront the precise data type that is to be used for the node's value. But in some cases, the situation is more complicated, and the problem domain calls for sub-types, a hierarchical structrue of data types. The picture below is a class diagram that shows example relations between three data types. The ScalarValueDataType and ArrayValueDataType inherit from a base data type, Structure.



When a node in such server then specifies its data type as Structure, there are three possible data types that the value can actually have: Structure, ScalarValueDataType, or ArrayValueDataType.

When the generic object is obtained from the server (such as by reads and subscriptions), the component always fills in the with a data type ID that is not UAModelNodeDescriptor.Null. When the generic object is to be transferred to the server (such as by writing), the component will use the data type ID provided, if it is not equal to UAModelNodeDescriptor.Null. Otherwise, the component will try to determine the data type (ID) itself, which may not work in case the actual data to be written are a sub-type of the node's data type (and which is always the case if the node's data type is abstract).

What do you need to take out of this discussion? That's actually easy:

- If you are just obtaining information from the server (reads, subscriptions), you need not to worry about the data type ID.
- If you are writing to the server, and the target node only allows value of single data type (no sub-types), you also do not need to worry about the data type ID.
- If you are writing to the server and the target node allows sub-types, you **have to** provide proper data type ID with the generic object, by filling in the DataTypeId Property.

How you obtain the data type ID depends on the application. For example

- You may know which server you are connecting to, and you will hard-code the necessary data type IDs into the program.
- You have previously obtained the generic data from the server, together with the its associated data type ID. In this case, you can simply pass that data type ID into the Write call.
- You can read the DataType attribute of the given node, either by regular Read methods on EasyUAClient Class, or using a handy extension method ReadDataType (or ReadMultipleDataTypes). As discussed above, this will only work if the actual data type you want is not a sub-type of the node's data type.
- You can navigate through the information model in the server, obtain available sub-types, and then have your application select from them.

The example below determines sub-types of a a given data type:

C#

```
// This example shows how to retrieve all sub-types of a given data type, recursively.

using System;
using OpcLabs.BaseLib.OperationModel.Generic;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.Extensions;

namespace UADocExamples._EasyUAClient

End Namespace
```

Note that this example shows both abstract and concrete data types. Only the concrete (= non-abstract) data types can be used for data transfer. You can determine whether a data type is abstract by reading the IsAbstract attribute of its data type ID node.

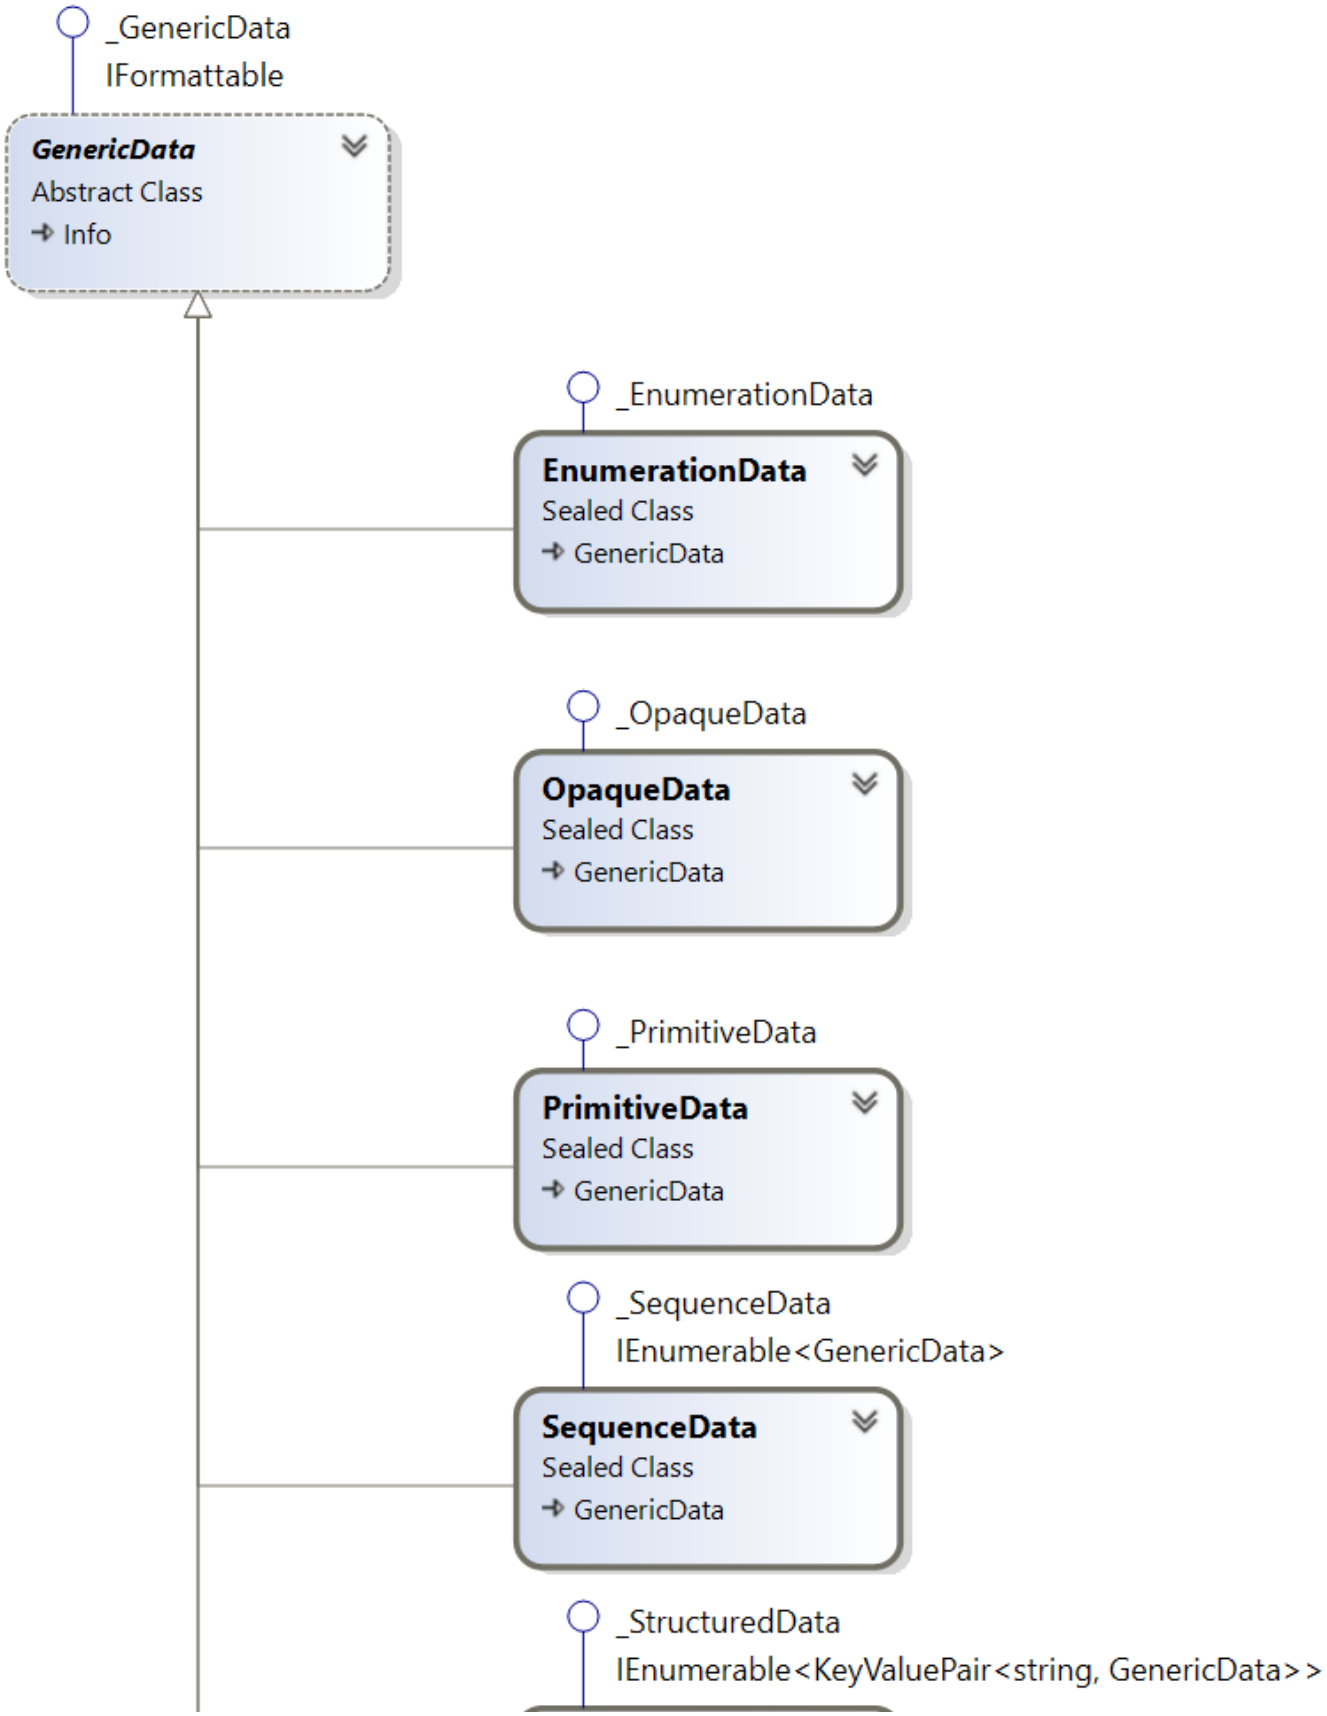
7.2.1.2 Generic data and data types

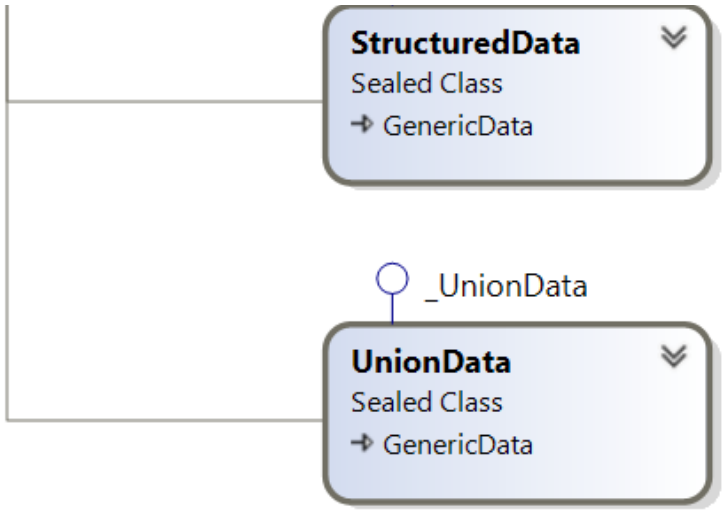
Generic data and data types is a set of classes that can be used to describe various simple and structured types commonly used in today's programming, and create objects that hold values of these types. The classes are designed so that you can easily create and process such generic data and data types, without them being tied to concrete platform or implementation.

7.2.1.2.1 Working with generic data

Generic data is represented by instances of types derived from the GenericData Class. The GenericData Class is a base abstract class that is concretized by its subtypes to enumerations, sequences, structures etc., as described in **Generic data kinds (Section 7.2.1.2.1.1)**.

In This Topic





Data type

Generic data can optionally have a *data type* associated with in, in its DataType Property. The data type provides metadata about what is contained in the generic data value itself. In addition, it provides a means to validate the generic data. Refer to **Generic data validation (Section 7.2.1.2.1.4)** for details on the validation.

> The data type assigned to the DataType Property of any generic value must always be the same as the kind of the generic data itself. For example, only enumeration data type can be assigned to enumeration generic data.
> The GenericData Class and its derivatives check the kind of data type being assigned automatically, and it is not possible to assign a data type of an incorrect kind to the DataType Property (an attempt to do so throws an exception). For this reason, checking the match of data type kinds versus is not necessary during and is not part of generic data validation.

Displaying generic data

When you invoke the ToString Method on some generic data object, or view it in the debugger, you will get a short, on-line rendering of the generic data. It contains the name of its data type (if available), its kind (such as 'structured' or 'enumerable'), and possibly some details specific to the generic data kind (such as the value of primitive data and the .NET type associated with ir, or a length of a sequence). You may get, for example:

```
(ScalarValueDataType) structured
```

If you want to see the information about the internals of the data type, you can use the "V" (verbose) format specifier. For example, this code (C#):

```
Console.WriteLine("{0:V}", genericData);
```

may produce following output (truncated):

```
(ScalarValueDataType) structured
  [BooleanValue] (Boolean) primitive; True {System.Boolean}
  [ByteStringValue] (ByteString) primitive; System.Byte[] {System.Byte[]}
  [ByteValue] (Byte) primitive; 153 {System.Byte}
```

```
  [DateTimeValue] (DateTime) primitive; 5/11/2013 4:32:00 PM {System.DateTime}
  [DoubleValue] (Double) primitive; -8.93178007363702E+27 {System.Double}
  [EnumerationValue] (Int32) primitive; 0 {System.Int32}
  [ExpandedNodeIdValue] (ExpandedNodeId) structured
    [NamespaceURI] (CharArray) primitive; "http://samples.org/UA/memorybuffer/Instance"
{System.String}
    [NamespaceURISpecified] (Bit) primitive; True {System.Boolean}
    [NodeIdType] (NodeIdType) enumeration; 3 (String)
    [ServerIndexSpecified] (Bit) primitive; False {System.Boolean}
    [String] (StringNodeId) structured
      [Identifier] (CharArray) primitive; "????" {System.String}
      [NamespaceIndex] (UInt16) primitive; 0 {System.UInt16}
  [FloatValue] (Float) primitive; 78.37176 {System.Single}
  [GuidValue] (Guid) primitive; 8129cdaf-24d9-8140-64f2-3a6d7a957fd7 {System.Guid}
  [Int16Value] (Int16) primitive; 2793 {System.Int16}
  [Int32Value] (Int32) primitive; 1133391074 {System.Int32}
  [Int64Value] (Int64) primitive; -1039109760798965779 {System.Int64}
  [Integer] (Variant) structured
    [ArrayDimensionsSpecified] sequence[1]
      [0] (Bit) primitive; False {System.Boolean}
    [ArrayLengthSpecified] sequence[1]
      [0] (Bit) primitive; False {System.Boolean}
    [Int64] sequence[1]
      [0] (Int64) primitive; 0 {System.Int64}
    [VariantType] sequence[6]
      [0] (Bit) primitive; False {System.Boolean}
      [1] (Bit) primitive; False {System.Boolean}
      [2] (Bit) primitive; False {System.Boolean}
      [3] (Bit) primitive; True {System.Boolean}
      [4] (Bit) primitive; False {System.Boolean}
      [5] (Bit) primitive; False {System.Boolean}
  [LocalizedTextValue] (LocalizedText) structured
    [Locale] (CharArray) primitive; "ko" {System.String}
    [LocaleSpecified] (Bit) primitive; True {System.Boolean}
    [Reserved1] sequence[6]
      [0] (Bit) primitive; False {System.Boolean}
      [1] (Bit) primitive; False {System.Boolean}
      [2] (Bit) primitive; False {System.Boolean}
      [3] (Bit) primitive; False {System.Boolean}
      [4] (Bit) primitive; False {System.Boolean}
      [5] (Bit) primitive; False {System.Boolean}
    [Text] (CharArray) primitive; "? ?? ??+ ??? ??) ?: ???? ?! ?!" {System.String}
    [TextSpecified] (Bit) primitive; True {System.Boolean}
  [NodeIdValue] (NodeId) structured
```

If you want to see the internals of the generic data in debugger, you can, of course, inspect its properties, sub-properties and so on. That can be quite a tedious task. For a quick overview, you can view the generic data in the same format as with the "V" (verbose) format specifier. To do so, find the DebugView property of the generic data, and display its contents (possibly using the Text Visualizer in Visual Studio debugger). Note that the DebugView property is private, and therefore is not listed in the reference documentation for the component.

7.2.1.2.1.1 Generic data kinds

Generic data can be of several different kinds: enumeration, opaque, primitive, sequence, structured, or union. You can determine the kind of generic data you are dealing with either by testing it actual type, or using its DataTypeKind

Property. The following table describes the generic data kinds available, and their associated concrete generic data classes.

DataTypeKind member	Associated generic data class
Enumeration	EnumerationData Class
Opaque	OpaqueData Class
Primitive	PrimitiveData Class
Sequence	SequenceData Class
Structured	StructuredData Class
Union	UnionData Class

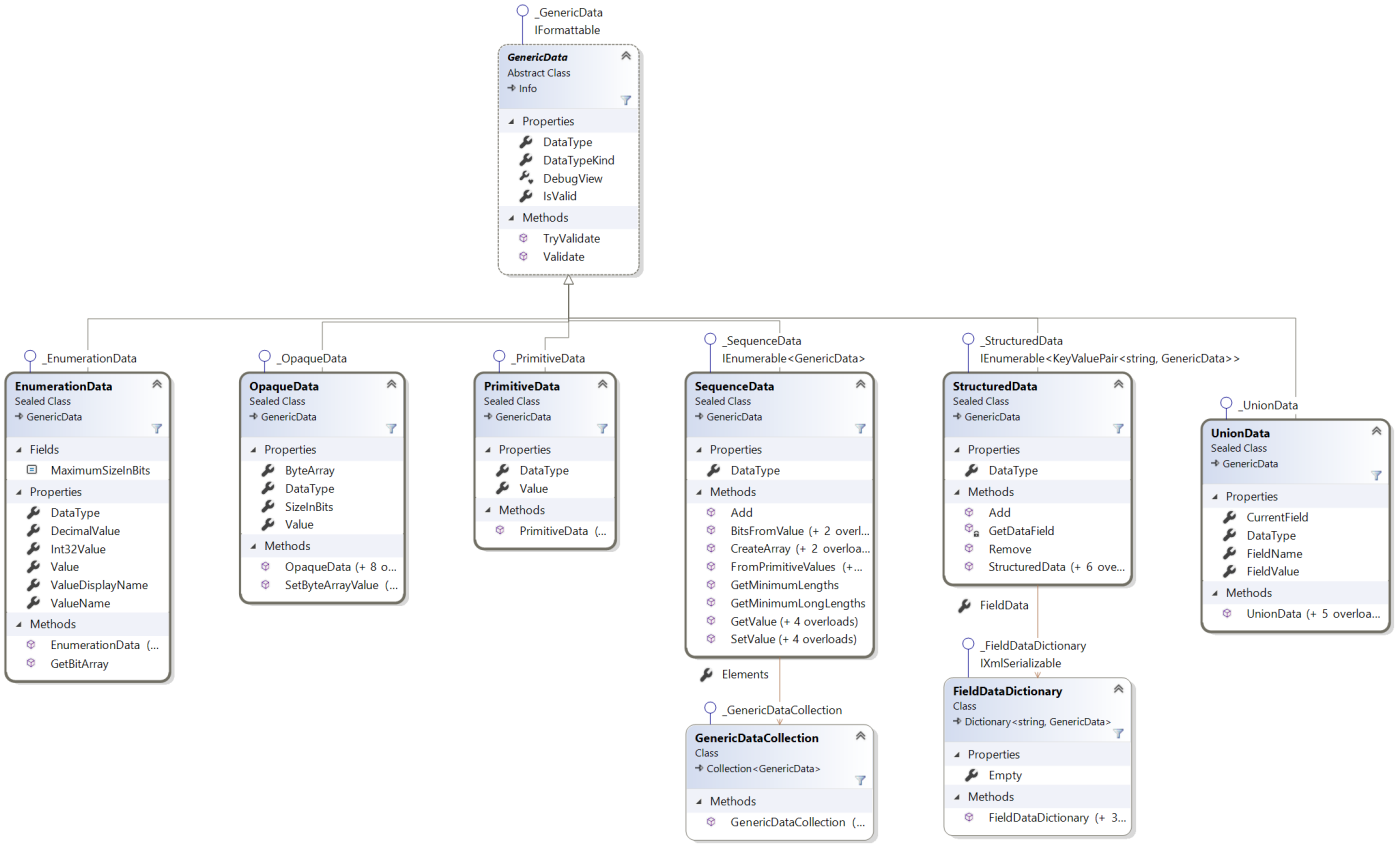
> In data type dictionary model (the only model before OPC UA 1.04), union data is not directly available. A union can, however, be quite efficiently modeled using an appropriately formed structure with optional fields.

For each kind of data type, there is also an associated data type class. See **Data type kinds (Section 7.2.1.2.2.1)** for more details. Note that if there is a data type associated with the generic data (by the means of non-null reference in its DataType Property), the kind of generic data always equals to the kind of the associated data type - this is guaranteed.

Here you will find more information to the specific data kinds:

- **Enumeration data (Section 7.2.1.2.1.1.1)**
- **Opaque data (Section 7.2.1.2.1.1.2)**
- **Primitive data (Section 7.2.1.2.1.1.3)**
- **Sequence data (Section 7.2.1.2.1.1.4)**
- **Structured data (Section 7.2.1.2.1.1.5)**
- **Union data (Section 7.2.1.2.1.1.6)**

The following class diagram shows the generic data clases and their relevant members:



7.2.1.2.1.1.1 Enumeration data

The enumeration data consists of a numeric, optionally also named value, chosen from a specified set of values. It is represented by an instance of the EnumerationData Class.

The Value Property contains the current enumeration value - an integer (64-bits).

If a data type is associated and it has a name for the value, the name is available in the ValueName Property.

7.2.1.2.1.1.2 Opaque data

The opaque data is data whose concrete representation is hidden from its users. It is represented by an instance of the OpaqueData Class. Internally, it keeps the actual data in a System.Collections.BitArray object. The size is given in bits (you can obtained in by getting the value of the SizeInBits Property).

The data is accessible through the Value Property. If you would rather access the data as a regular array of bytes rather than a bit array, you can get the ByteArray Property to do so. If you want to set the whole byte array to a value of your own, use the SetByteArrayValue Method; this is not a property setter because it also requires the size in bits (which does not have to represent a whole number of bytes) be specified.

Note, however, that the two representations (the bit array and the byte array) are not internally synchronized. Setting a bit or byte in one of them does not set the other. Assigning a wholly new value to one of them causes the other be later re-created with a copy of the source data.

7.2.1.2.1.1.3 Primitive data

The primitive data is a value given in the underlying (.NET) type system. It is represented by an instance of the PrimitiveData Class.

The actual primitive value is stored in the Value Property and it can be any System.Object.

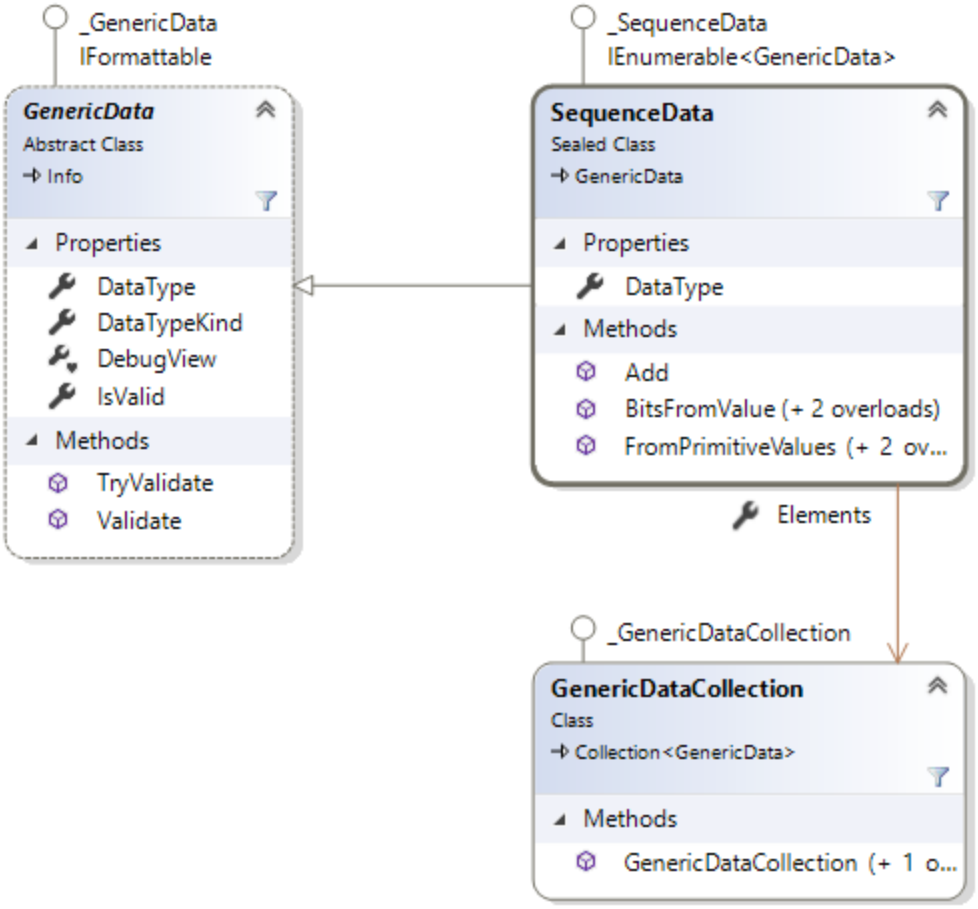
The OPC UA Complex Data extension contains intrinsic data type dictionaries that map specific standard and commonly used data types to primitive data types. For details, refer to **OPC UA Data Type Systems (Section 7.2.1.3)**.

7.2.1.2.1.1.4 Sequence data

The sequence data is an ordered collection of values. It is represented by an instance of the SequenceData Class.

The elements of the sequence data are contained in the Elements Property.

The SequenceData Class is an IEnumerable of GenericData (its elements), and it has an Add Method for the same. It means that you can easily enumerate through its elements, and it can also participate in collection initializers in C# or in VB.NET.



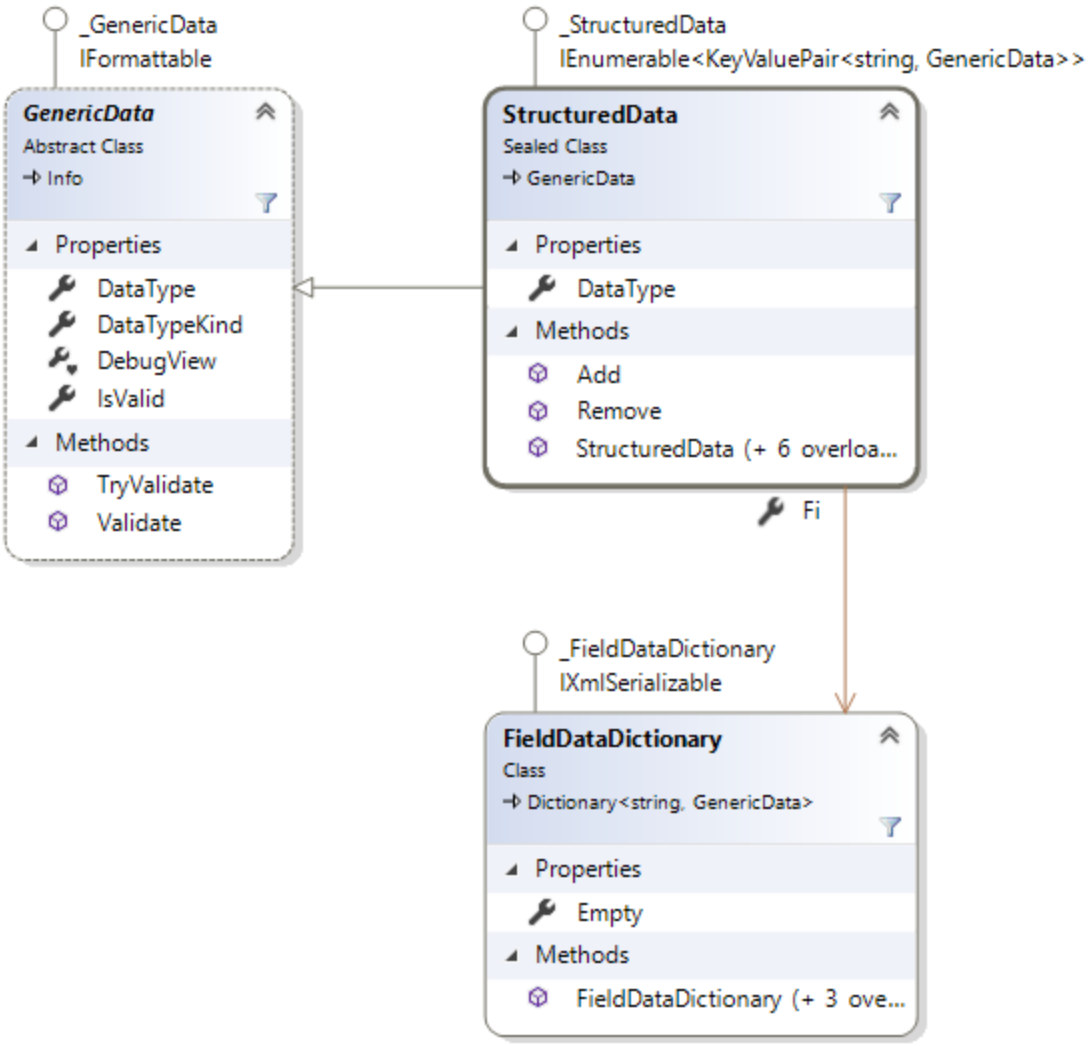
7.2.1.2.1.1.5 Structured data

The structured data is a record, or a representation of union (in data dictionary model, i.e. the only model available before

OPC UA 1.04). It is represented by an instance of the StructuredData Class.

The FieldData Property contains *field data* - a dictionary where the key is a field name, and the value is a generic data of that field.

The StructuredData Class is an IEnumerable of KeyValuePair<String, GenericData> (its field data), and it has an Add Method for the same. It means that you can easily enumerate through its field data, and it can also participate in collection initializers in C# or in VB.NET.



OptionSets

OPC UA has a concept of *OptionSets*. *OptionSet* value is basically a group of named bits. Some *OptionSets* may have an associated validity mask, which determines which of the bits are valid (when reading) or which bits should be written.

OPC Data Client represents *OptionSets* as structures of Boolean values, where each data field of the structure corresponds to one bit of the *OptionSet*. All data fields are optional, and data fields for bits that not contained in the validity mask are omitted from the data.

7.2.1.2.1.1.6 Union data

A (tagged) union contains a single value out of several possible fields (or no value at all). It is represented by an instance UnionData Class.

> In data type dictionary model (the only model before OPC UA 1.04), union data is not directly available. A union can, however, be quite efficiently modeled using an appropriately formed structure with optional fields.

The string FieldName Property contain the name of the field currently contained in the union (this is the "tag" of the union). An empty string in this property denotes a union that currently contains no data.

The FieldValue Property contains the value of the field currently selected in the union.

7.2.1.2.1.2 Creating generic data

You create generic data objects simply by calling their constructors with appropriate arguments, and possibly filling in additional properties that were not passed into the constructors.

The example below shows how different kinds of generic data can be created.

C#

```
// This example shows different ways of constructing generic data.

using System;
using System.Collections;
using OpcLabs.BaseLib.DataTypeModel;

namespace UADocExamples.ComplexData._GenericData
{
    class _Construction
    {
        public static void Main1()
        {
            // Create enumeration data with value of 1.
            var enumerationData = new EnumerationData(1);
            Console.WriteLine(enumerationData);

            // Create opaque data from an array of 2 bytes, specifying its size as 15
bits.
            var opaqueData1 = new OpaqueData(new byte[] {0xAA, 0x55}, sizeInBits:15);
            Console.WriteLine(opaqueData1);

            // Create opaque data from a bit array.
            var opaqueData2 = new OpaqueData(new BitArray(new[] { false, true, false,
true, false }));
            Console.WriteLine(opaqueData2);

            // Create primitive data with System.Double value of 180.0.
            var primitiveData1 = new PrimitiveData(180.0d);
            Console.WriteLine(primitiveData1);

            // Create primitive data with System.String value.
```

```
            var primitiveData2 = new PrimitiveData("Temperature is too high!");
            Console.WriteLine(primitiveData2);

            // Create sequence data with two elements, using collection initializer
syntax.
            var sequenceData1 = new SequenceData
            {
                opaqueData1,
                opaqueData2
            };
            Console.WriteLine(sequenceData1);

            // Create the same sequence data, using the Add method.
            var sequenceData2 = new SequenceData();
            sequenceData2.Elements.Add(opaqueData1);
            sequenceData2.Elements.Add(opaqueData2);
            Console.WriteLine(sequenceData2);

            // Create the same sequence data, using an array (an enumerable) of its
elements.
            var sequenceData3 = new SequenceData(
                new GenericDataCollection(new[] {opaqueData1, opaqueData2}));
            Console.WriteLine(sequenceData3);

            // Create structured data with two members, using collection initializer
syntax.
            var structuredData1 = new StructuredData
            {
                {"Message", primitiveData2},
                {"Status", enumerationData}
            };
            Console.WriteLine(structuredData1);

            // Create the same structured data using the Add method.
            var structuredData2 = new StructuredData();
            structuredData2.Add("Message", primitiveData2);
            structuredData2.Add("Status", enumerationData);
            Console.WriteLine(structuredData2);

            // Create union data.
            var unionData1 = new UnionData("DoubleField", primitiveData1);
            Console.WriteLine(unionData1);
        }
    }
}
```

Object Pascal

```
// This example shows different ways of constructing generic data.

class procedure _Construction.Main;
var
  ByteArray1, ByteArray2: OleVariant;
  EnumerationData: _EnumerationData;
  OpaqueData1, OpaqueData2: _OpaqueData;
  PrimitiveData1, PrimitiveData2: _PrimitiveData;
  SequenceData1: _SequenceData;
```

```
  StructuredData1: _StructuredData;
begin
  // Create enumeration data with value of 1.
  EnumerationData := CoEnumerationData.Create;
  EnumerationData.Value := 1;
  WriteLn(EnumerationData.ToString);

  // Create opaque data from an array of 2 bytes, specifying its size as 15 bits.
  OpaqueData1 := CoOpaqueData.Create;
  ByteArray1 := VarArrayCreate([0, 1], varVariant);
  ByteArray1[0] := $AA;
  ByteArray1[1] := $55;
  OpaqueData1.SetByteArrayValue(ByteArray1, 15);
  WriteLn(OpaqueData1.ToString);
  // Create opaque data from an array of 1 bytes, specifying its size as 5 bits.
  OpaqueData2 := CoOpaqueData.Create;
  ByteArray2 := VarArrayCreate([0, 0], varVariant);
  ByteArray2[0] := $A;
  OpaqueData2.SetByteArrayValue(ByteArray2, 5);
  WriteLn(OpaqueData2.ToString);

  // Create primitive data with System.Double value of 180.0.
  PrimitiveData1 := CoPrimitiveData.Create;
  PrimitiveData1.Value := 180.0;
  WriteLn(PrimitiveData1.ToString);

  // Create primitive data with System.String value.
  PrimitiveData2 := CoPrimitiveData.Create;
  PrimitiveData2.Value := 'Temperature is too high!';
  WriteLn(PrimitiveData2.ToString);

  // Create sequence data with two elements, using the Add method.
  SequenceData1 := CoSequenceData.Create;
  SequenceData1.Elements.Add(OpaqueData1);
  SequenceData1.Elements.Add(OpaqueData2);
  WriteLn(SequenceData1.ToString);

  // Create structured data with two members, using the Add method.
  StructuredData1 := CoStructuredData.Create;
  StructuredData1.Add('Message', PrimitiveData2);
  StructuredData1.Add('Status', EnumerationData);
  WriteLn(StructuredData1.ToString);
end;
```

PHP

```
// This example shows different ways of constructing generic data.

// Create enumeration data with value of 1.
$EnumerationData = new COM("OpcLabs.BaseLib.DataTypeModel.EnumerationData");
$EnumerationData->Value = 1;
printf("%s\n", $EnumerationData);

// Create opaque data from an array of 2 bytes, specifying its size as 15 bits.
$OpaqueData1 = new COM("OpcLabs.BaseLib.DataTypeModel.OpaqueData");
$ByteArray1[0] = 0xAA;
$ByteArray1[1] = 0x55;
```

```
$OpaqueData1->SetByteArrayValue($ByteArray1, 15);
printf("%s\n", $OpaqueData1);

// Create opaque data from a bit array.
$OpaqueData2 = new COM("OpcLabs.BaseLib.DataTypeModel.OpaqueData");
$BitArray = $OpaqueData2->Value;
$BitArray->Length = 5;
$BitArray->Set(0, false);
$BitArray->Set(1, true);
$BitArray->Set(2, false);
$BitArray->Set(3, true);
$BitArray->Set(4, false);
printf("%s\n", $OpaqueData2);

// Create primitive data with System.Double value of 180.0.
$PrimitiveData1 = new COM("OpcLabs.BaseLib.DataTypeModel.PrimitiveData");
$PrimitiveData1->Value = 180.0;
printf("%s\n", $PrimitiveData1);

// Create primitive data with System.String value.
$PrimitiveData2 = new COM("OpcLabs.BaseLib.DataTypeModel.PrimitiveData");
$PrimitiveData2->Value = "Temperature is too high!";
printf("%s\n", $PrimitiveData2);

// Create sequence data with two elements, using the Add method.
$SequenceData1 = new COM("OpcLabs.BaseLib.DataTypeModel.SequenceData");
$SequenceData1->Elements->Add($OpaqueData1);
$SequenceData1->Elements->Add($OpaqueData2);
printf("%s\n", $SequenceData1);

// Create structured data with two members, using the Add method.
$StructuredData1 = new COM("OpcLabs.BaseLib.DataTypeModel.StructuredData");
$StructuredData1->Add("Message", $PrimitiveData2);
$StructuredData1->Add("Status", $EnumerationData);
printf("%s\n", $StructuredData1);
```

VB.NET

```
' This example shows different ways of constructing generic data.

Imports System
Imports System.Collections
Imports OpcLabs.BaseLib.DataTypeModel

Namespace UADocExamples.ComplexData._GenericData

    Friend Class _Construction

        Public Shared Sub Main1()
            ' Create enumeration data with value of 1.
            Dim enumerationData = New EnumerationData(1)
            Console.WriteLine(enumerationData)

            ' Create opaque data from an array of 2 bytes, specifying its size as 15
bits.
            Dim opaqueData1 = New OpaqueData(New Byte() {170, 85}, sizeInBits:=15)
            Console.WriteLine(opaqueData1)
```

```
            ' Create opaque data from a bit array.
            Dim opaqueData2 = New OpaqueData(New BitArray(New Boolean() {False, True,
False, True, False}))
            Console.WriteLine(opaqueData2)

            Console.WriteLine(structuredData2)
        End Sub
    End Class
End Namespace
```

VBScript

```
Rem This example shows different ways of constructing generic data.

Option Explicit

' Create enumeration data with value of 1.
Dim EnumerationData: Set EnumerationData =
CreateObject("OpcLabs.BaseLib.DataTypeModel.EnumerationData")
EnumerationData.Value = 1
```

```
WScript.Echo EnumerationData

' Create opaque data from an array of 2 bytes, specifying its size as 15 bits.
Dim OpaqueData1: Set OpaqueData1 =
CreateObject("OpcLabs.BaseLib.DataTypeModel.OpaqueData")
OpaqueData1.SetByteArrayValue Array(&HAA, &H55), 15
WScript.Echo OpaqueData1

' Create opaque data from a bit array.
Dim OpaqueData2: Set OpaqueData2 =
CreateObject("OpcLabs.BaseLib.DataTypeModel.OpaqueData")
Dim BitArray: Set BitArray = OpaqueData2.Value
BitArray.Length = 5
BitArray(0) = False
BitArray(1) = True
BitArray(2) = False
BitArray(3) = True
BitArray(4) = False
WScript.Echo OpaqueData2

' Create primitive data with System.Double value of 180.0.
Dim PrimitiveData1: Set PrimitiveData1 =
CreateObject("OpcLabs.BaseLib.DataTypeModel.PrimitiveData")
PrimitiveData1.Value = 180.0
WScript.Echo PrimitiveData1

' Create primitive data with System.String value.
Dim PrimitiveData2: Set PrimitiveData2 =
CreateObject("OpcLabs.BaseLib.DataTypeModel.PrimitiveData")
PrimitiveData2.Value = "Temperature is too high!"
WScript.Echo PrimitiveData2

' Create sequence data with two elements, using the Add method.
Dim SequenceData1: Set SequenceData1 =
CreateObject("OpcLabs.BaseLib.DataTypeModel.SequenceData")
SequenceData1.Elements.Add OpaqueData1
SequenceData1.Elements.Add OpaqueData2
WScript.Echo SequenceData1

' Create structured data with two members, using the Add method.
Dim StructuredData1: Set StructuredData1 =
CreateObject("OpcLabs.BaseLib.DataTypeModel.StructuredData")
StructuredData1.Add "Message", PrimitiveData2
StructuredData1.Add "Status", EnumerationData
WScript.Echo StructuredData1
```

7.2.1.2.1.3 Processing generic data

In order to process generic data (a sub-type of GenericData Class), you need to first determine its kind (see **Generic data kinds (Section 7.2.1.2.1.1)**). You can do it by

- getting its DataTypeKind Property, and then having a switch or other kind of conditional statement, taking care of different data type kinds, or

- attempting to cast it (e.g. using the as operator in C#, or TryCast in VB.NET) to a concrete generic data class (e.g. StructuredData), and testing whether it has succeeded.

All generic data classes share a common DataType Property, which contains an optional data type object.

After you have determined the kind of generic data you are dealing with, you can use the generic data object cast to appropriate type, and work with properties and methods that are specific to that data type kind. For example, SequenceData contains the elements of the sequence in its Elements Property.

The following example shows how generic data can be processed.

C#

```
// Shows how to process generic data type, displaying some of its properties,
recursively.

using System;
using System.Collections.Generic;
using OpcLabs.BaseLib.DataTypeModel;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.ComplexData;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.ComplexData._GenericData

```
                Case DataTypeKind.Union
                    Console.WriteLine("The generic data is union.")
                    Dim unionData = CType(genericData, UnionData)
                    Console.WriteLine("The name of current field is: {0}",
unionData.FieldName)
                    Console.WriteLine("Current field value is: {0}",
unionData.FieldValue)
            End Select

        End Sub
    End Class
End Namespace
```

In many cases, you will not be processing the generic data alone, but in parallel with the data type. See **Processing data types (Section 7.2.1.2.2.3)** for details.

7.2.1.2.1.4 Generic data validation

When the GenericData is returned from the server by the component (e.g. from read operations or by subscriptions), its DataType Property property is always filled in (i.e. not null).

When the GenericData is passed in to the component for transfer to the server (e.g. to a write operation), filling in the DataType Property optional. When not null, the component checks the value in GenericDataagainst the data type given by this property, and issues an error if the value does not conform to the type. It is allowed for this property to be not null at some higher level, and be null at lower level, such as for an individual field of a structure.

In This Topic

When the data type is given and passed to the component, it is only used for the checks described above. It does not influence the actual encoding of the values, and the encoding process may further reject some input values as not conforming to the encoding.

Validation rules

Generic data can only be validated if it has a non-null DataType associated with it. When the DataType is null, the validation always succeeds.

For all kinds of generic data, the associated data type must be **complete** and **terminable** for the validation to succeed. For discussions of these terms, see **Working with data types (Section 7.2.1.2.2)**.

Besides these common rules, specific rules apply to different kinds of generic data:

- For enumeration data, if the size in bits (SizeInBits Property) is given in the data type (is non-negative), the actual value must not exceed the size that fits into the number of bits given by the data type.
- For opaque data, if the size in bits (SizeInBits Property in the OpaqueDataType Class) is given in the data type (is non-negative), the actual size in bits of the opaque value must be precisely equal to the size given by the data type.
- Primitive data is always valid.
- For sequence data, all elements must be non-null and also valid. In addition, if a length is given in the data type

(Length Property), the actual count of elements in the sequence must be precisely equal to the length given by the data type.
- For structured data, all field values must be non-null and also valid. In addition, all mandatory (non-optional), non-length fields that are defined by the data type must also be present in the actual field data (FieldData Property).
- For union data, if the FieldName Property (current field name) is empty, the current union value (the FieldValue Property) must be null. If the FieldName Property (current field name) is not empty, it must correspond to one of the data fields in the DataFields Property. This data field must not be a length field or switch field and must not be optional, and its data value must be null.

Invoking the validation

You can also invoke the validation of generic data from your code, e.g. to prevent errors upon writing the data. To do so, you can do one of the following:

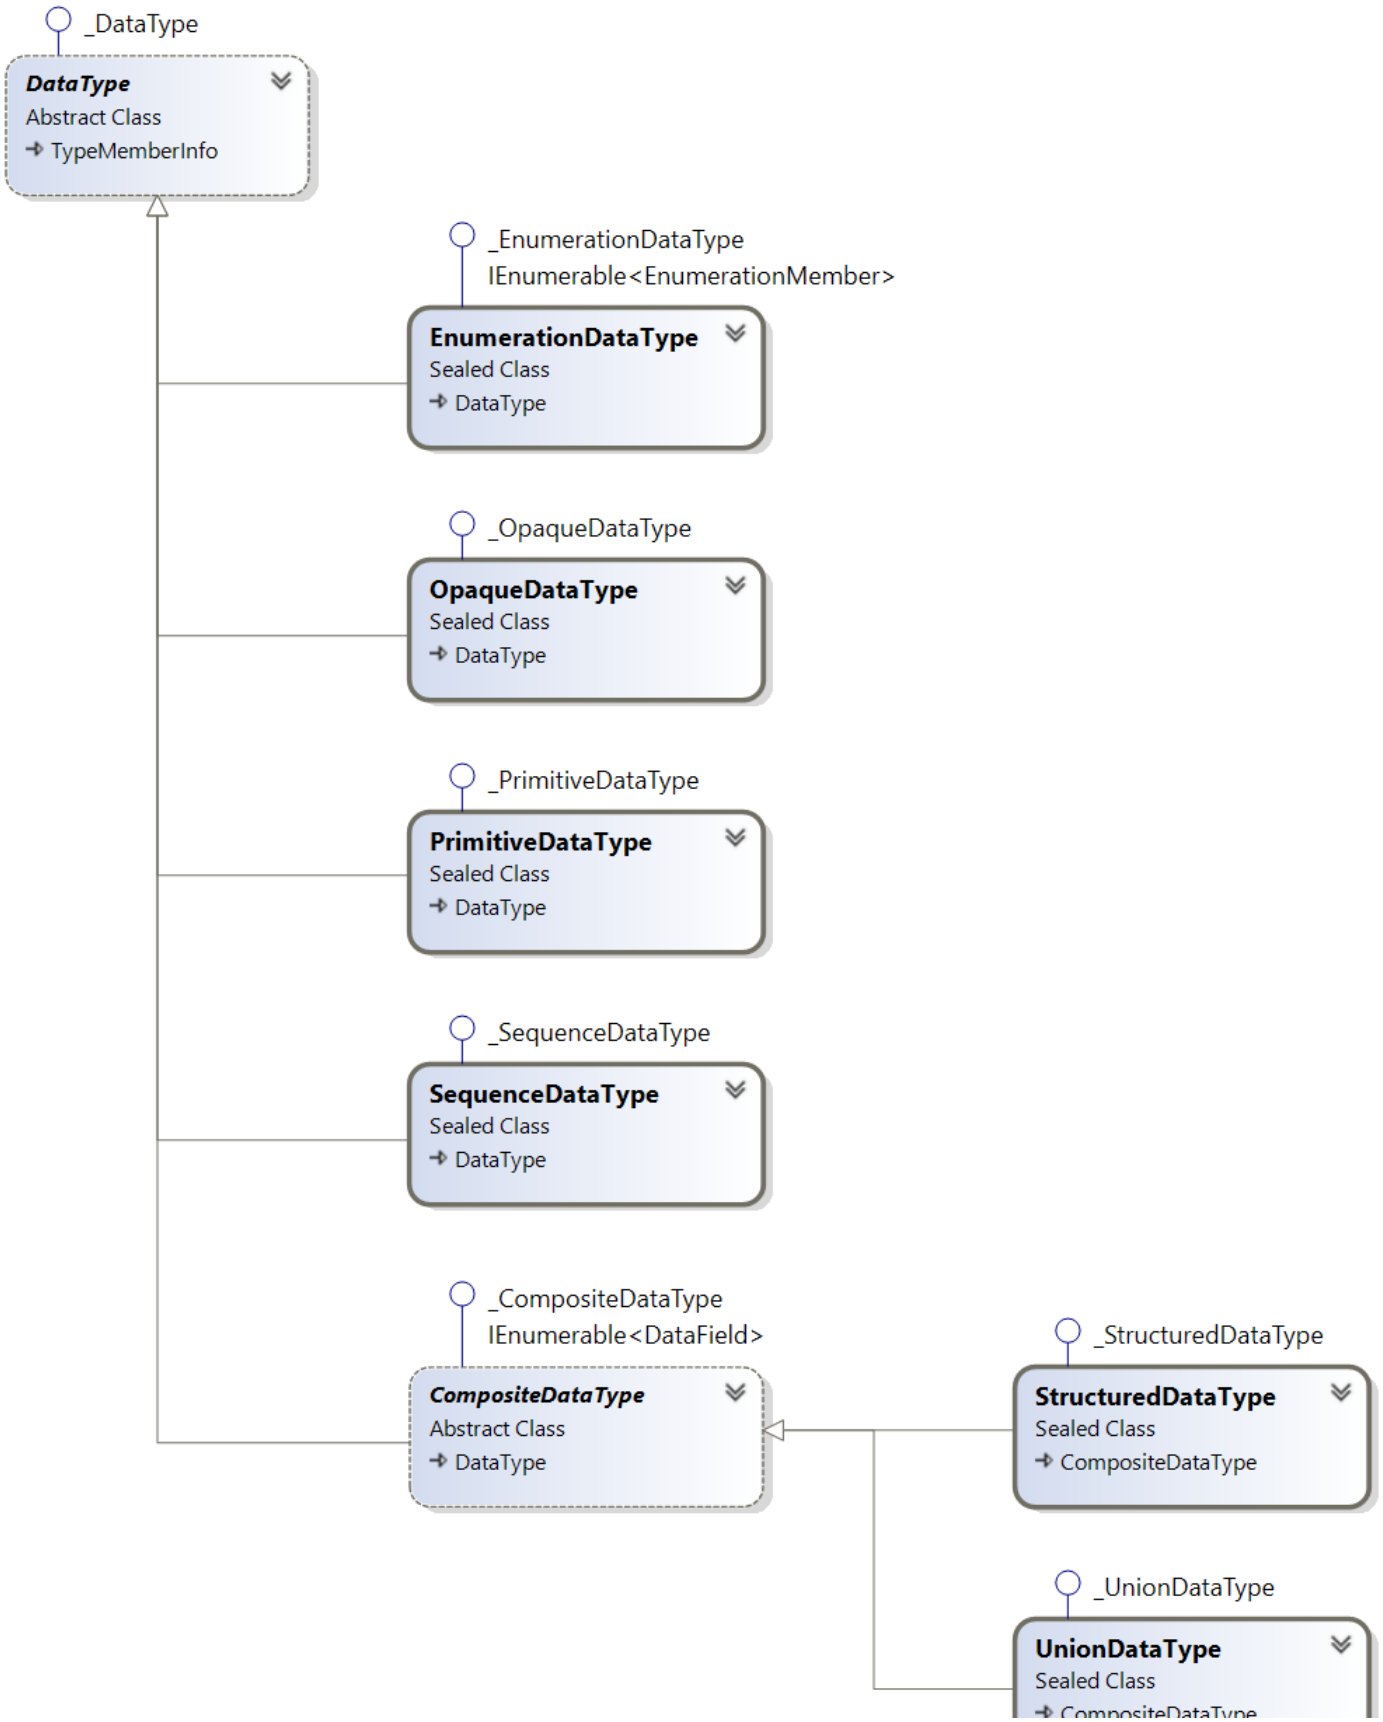
- Inspect the IsValid Property of the generic data. The return value (a boolean) indicates whether the current data is valid.
- Call the TryValidate Method on the generic data. This method attempts to validate the current data. It returns a non-null Exception if the validations fails; it returns a null reference otherwise.
- Call the Validate Method on the generic data. This method validates the current data. It throws an exception when the validation fails.

7.2.1.2.2 Working with data types

A data type is represented by an instance of some type derived from the DataType Class. The DataType Class itself is abstract, but there are several concrete classes that derive from it.

Data types can be of several different kinds: enumeration, opaque, primitive, sequence, or structured. Refer to **Data type kinds (Section 7.2.1.2.2.1)** for mode details on the individual kinds. You can determine the kind of data type you are dealing with either by testing it actual type, or using its Kind Property.

In This Topic



Refer to **Creating data types (Section 7.2.1.2.2.2)** if you need to create an instance of some data type (derived from the DataType Class; that is actually rare, maybe just for generic data validation purposes - see **Generic data validation (Section 7.2.1.2.1.4)**). If you need to process a data type object that you have obtained from the comonent, refer to **Processing data types (Section 7.2.1.2.2.3)**.

Recursive data types

The data type is **recursive** when it contains a cycle, directly or indirectly. For example, a structured data type may contain a field that is a sequence of the same data type. Recursive data types as such are not invalid, and are even not so uncommon; for example, the Variant data type is defined recursively. You can determine whether the data type is recursive using its IsRecursive Property.

For the data type to be usable, however, it must be **terminable**. The data type is terminable if it is capable of producing finite data. All non-recursive data types are terminable, but not all recursive types are. For example, in the example with a structured data type above, the data type would be terminable if the field was optional, or if the length of the sequence was not fixed (and could be zero). In such cases the expansion of the data type can be stopped at some point, by omitting the field form the data, or having a zero length sequence. If, however, the field was mandatory and the sequence had a fixed non-zero length, such data type would not be terminable - and would be basically useless, because the only data it can describe is infinite.

You can determine whether a data type is terminable using its IsTerminable Property.

Incomplete types

The data type is **complete** when all its constituent data type are filled in are are themselves complete. For example, the field in the structured data type must have their types defined by a non-null data type.

Normally, when data types are constructed, you create them already as complete. But in order construct recursive data types, an incomplete data type needs to be created first, and the loop - the missing data type - is closed later. Incomplete data types should therefore exist only temporarily, during their construction. They must not participate in further operations, and generic data is invalid for operations when it has an incomplete data type associated with it - see **Generic data validation (Section 7.2.1.2.1.4)**.

You can determine whether a data type is complete using its IsComplete Property.

Displaying data types

When you invoke the ToString Method on some data type, or view it in the debugger, you will get a short, on-line rendering of the data type. It contains its name (if it has a name), its kind (such as 'structured' or 'enumerable'), and possibly some details specific to the data type kind (such as the .NET type associated with primitive data). You may get, for example:

```
(ScalarValueDataType) structured
```

If you want to see the information about the internals of the data type, you can use the "V" (verbose) format specifier. For example, this code (C#):

```
Console.WriteLine("{0:V}", dataType);
```

may produce following output (truncated):

```
ScalarValueDataType = structured
  [BooleanValue] Boolean = primitive(System.Boolean)
  [ByteStringValue] ByteString = primitive(System.Byte[])
  [ByteValue] Byte = primitive(System.Byte)
  [DateTimeValue] DateTime = primitive(System.DateTime)
  [DoubleValue] Double = primitive(System.Double)
  [EnumerationValue] Int32 = primitive(System.Int32)
  [ExpandedNodeIdValue] ExpandedNodeId = structured
    [ByteString] optional ByteStringNodeId = structured
    [Identifier] ByteString = primitive(System.Byte[])
      [NamespaceIndex] UInt16 = primitive(System.UInt16)
    [FourByte] optional FourByteNodeId = structured
      [Identifier] UInt16 = primitive(System.UInt16)
      [NamespaceIndex] Byte = primitive(System.Byte)
    [Guid] optional GuidNodeId = structured
      [Identifier] Guid = primitive(System.Guid)
      [NamespaceIndex] UInt16 = primitive(System.UInt16)
    [NamespaceURI] optional CharArray = primitive(System.String)
    [NamespaceURISpecified] switch Bit = primitive(System.Boolean)
    [NodeIdType] switch NodeIdType = enumeration(6)
      TwoByte = 0
      FourByte = 1
      Numeric = 2
      String = 3
      Guid = 4
      ByteString = 5
    [Numeric] optional NumericNodeId = structured
      [Identifier] UInt32 = primitive(System.UInt32)
      [NamespaceIndex] UInt16 = primitive(System.UInt16)
    [ServerIndex] optional UInt32 = primitive(System.UInt32)
    [ServerIndexSpecified] switch Bit = primitive(System.Boolean)
    [String] optional StringNodeId = structured
      [Identifier] CharArray = primitive(System.String)
      [NamespaceIndex] UInt16 = primitive(System.UInt16)
    [TwoByte] optional TwoByteNodeId = structured
    [Identifier] Byte = primitive(System.Byte)
  [FloatValue] Float = primitive(System.Single)
  [GuidValue] Guid = primitive(System.Guid)
  [Int16Value] Int16 = primitive(System.Int16)
  [Int32Value] Int32 = primitive(System.Int32)
  [Int64Value] Int64 = primitive(System.Int64)
  [Integer] Variant = structured
    [ArrayDimensions] optional sequence[*] of Int32 = primitive(System.Int32)
    [ArrayDimensionsSpecified] switch sequence[1] of Bit = primitive(System.Boolean)
    [ArrayLength] length optional Int32 = primitive(System.Int32)
    [ArrayLengthSpecified] switch sequence[1] of Bit = primitive(System.Boolean)
    [Boolean] optional sequence[*] of Boolean = primitive(System.Boolean)
    [Byte] optional sequence[*] of Byte = primitive(System.Byte)
```

The component will correctly (without looping infinitely) display recursive data types as well.

If you want to see the internals of the data type in debugger, you can, of course, inspect its properties, sub-properties and so on. That can be quite a tedious task. For a quick overview, you can view the data type in the same format as with the "V" (verbose) format specifier. To do so, find the DebugView property of the data type, and display its contents (possibly using the Text Visualizer in Visual Studio debugger). Note that the DebugView property is private, and therefore is not

listed in the reference documentation for the component.

7.2.1.2.2.1 Data type kinds

Data types can be of several different kinds: enumeration, opaque, primitive, sequence, or structured. You can determine the kind of data type you are dealing with either by testing it actual type, or using its Kind Property.

The following table describes the data type kinds available, and their associated concrete data type classes.

DataTypeKind member	Associated data type class
Enumeration	EnumerationDataType Class
Opaque	OpaqueDataType Class
Primitive	PrimitiveDataType Class
Sequence	SequenceDataType Class
Structured	StructuredDataType Class
Union	UnionDataType Class

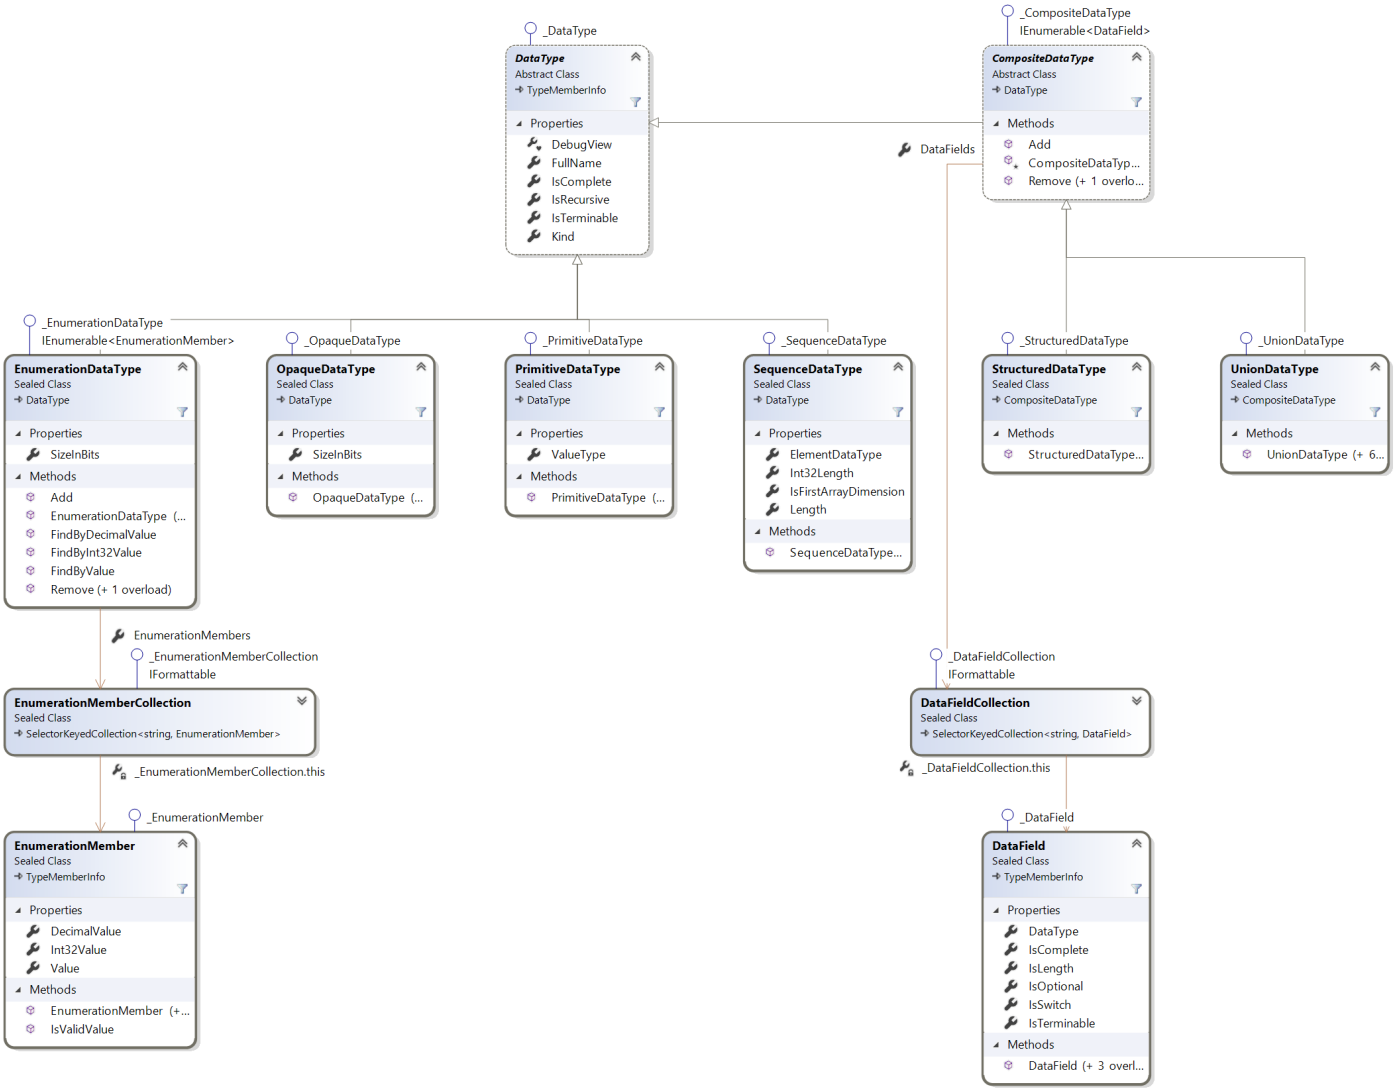
In data type dictionary model (the only model before OPC UA 1.04), union data is not directly available. A union can, however, be quite efficiently modeled using an appropriately formed structure with optional fields.

For each kind of data type, there is also an associated generic data class. See **Generic data kinds (Section 7.2.1.2.1.1)** for more details.

Here you will find more information to the specific data type kinds:

- **Enumeration data type (Section 7.2.1.2.2.1.1)**
- **Opaque data type (Section 7.2.1.2.2.1.2)**
- **Primitive data type (Section 7.2.1.2.2.1.3)**
- **Sequence data type (Section 7.2.1.2.2.1.4)**
- **Structured data type (Section 7.2.1.2.2.1.5)**
- **Union data type (Section 7.2.1.2.2.1.6)**

The following class diagram shows the data type classes and their relevant members:



7.2.1.2.2.1.1 Enumeration data type

The enumeration data type is a data type consisting of a set of named values. It is represented by an instance of the EnumerationDataType Class.

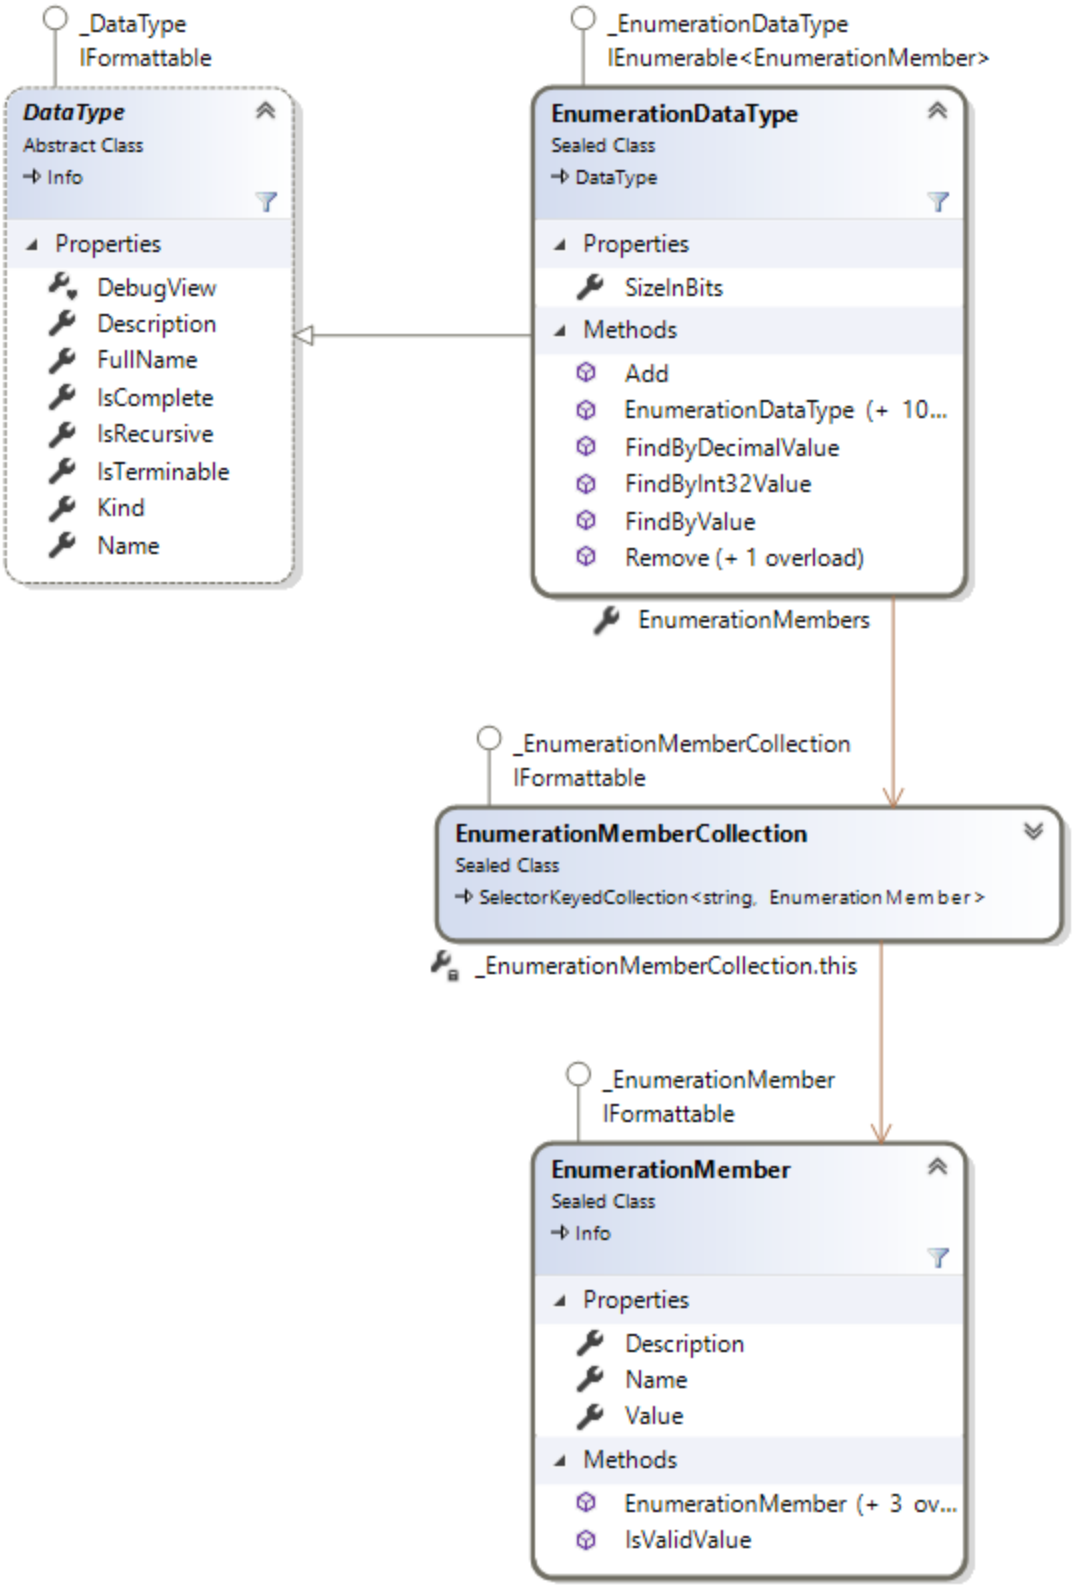
The SizeInBits Property determines how many bits the enumeration value can occupy. It is set to -1 when the size is unknown.

The EnumerationMembers Property contains a collection of enumeration members, i.e. descriptions of possible enumeration values. Each such description is an instance of EnumerationMember Class, and specifies:

- The Value: The actual integer value of the enumeration member.
- The Name: A short descriptive name of the enumeration member.
- The Description: Human readable description of the enumeration members.

Note that having the enumeration members in the EnumerationMembers Property is purely optional from the perspective of validation the generic data against the data type (see **Generic data validation (Section 7.2.1.2.1.4)**). Any enumeration value that first into the given size in bits (if specified) is valid.

The EnumerationDataType Class is an IEnumerable of EnumerationMember, and it has an Add Method for the same. It means that you can easily enumerate through its members, and it can also participate in collection initializers in C# or in VB.NET.



7.2.1.2.2.1.2 Opaque data type

The opaque data type is a data type whose concrete representation is hidden from its users. It is represented by an instance of the OpaqueDataType Class.

The SizeInBits Property determines how many bits the opaque value occupies. It equals to -1 when the size in unknown.

7.2.1.2.2.1.3 Primitive data type

The primitive data type is a basic or built-in type of the data type system. It is represented by an instance of the PrimitiveDataType Class.

The ValueType Property contains the .NET type of values represented by that instance. It can be, for example, System.Byte type.

The OPC UA Complex Data extension contains intrinsic data type dictionaries that map specific standard and commonly used data types to primitive data types. For details, refer to **OPC UA Data Type Systems (Section 7.2.1.3)**. You can therefore expect these primitive data types to appear in the complex data that you get from the server. Conversely, when you are sending some complex data to the server, your choice of primitive data types is limited by what the server supports.

7.2.1.2.2.1.4 Sequence data type

The sequence data type is a data type that represents a countable number of ordered values. It is represented by an instance of the SequenceDataType Class.

The ElementDataType Property contains the data type of the elements of the sequence.

The Length Property determines how many elements the sequence has. It is equals to -1 when the length is unknown (e.g. dynamic).

7.2.1.2.2.1.5 Structured data type

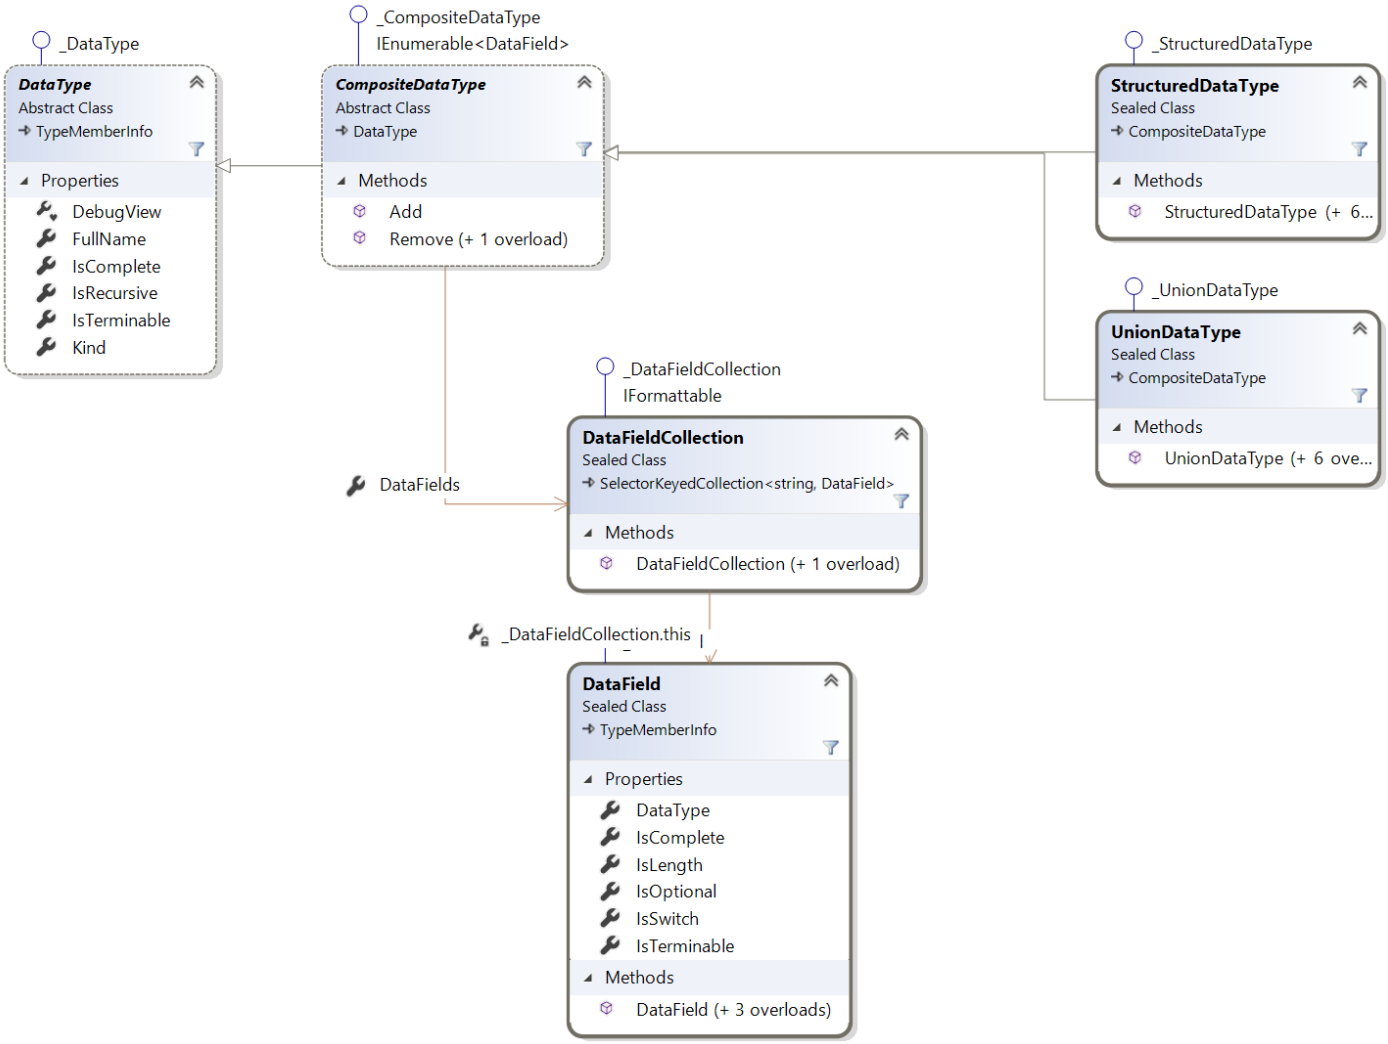
The structured data type is a record or a representation of union (in data dictionary model, i.e. the only model available before OPC UA 1.04). It is represented by an instance of the StructuredDataType Class.

The DataFields Property contains a collection of data fields of the structured data type. Each such data field is an instance of DataField Class, and specifies:

- A DataType of the contents of the field.
- A Name: Data field name, unique within the structured data type.
- A Description: Human readable description of the data field.
- An IsLength flag: Determines whether the field denotes a length of some sequence. Length fields may have special behavior e.g. with respect to **Generic data auto-complete (Section 7.2.1.3.1)**, and in validation of generic data (see **Generic data validation (Section 7.2.1.2.1.4)**).
- An IsOptional flag: Determines whether the field can be omitted from the encoded data. Optional fields play role role in determining whether a recursive data type is terminable (see **Working with data types (Section 7.2.1.2.2)**) and in validation of generic data (see **Generic data validation (Section 7.2.1.2.1.4)**).
- An IsSwitch flag: Determines whether the field acts as a switch for some other field. Switch fields may have special

behavior e.g. with respect to **Generic data auto-complete (Section 7.2.1.3.1)**.

The StructuredDataType Class is an IEnumerable of DataField, and it has an Add Method for the same. It means that you can easily enumerate through its data fields, and it can also participate in collection initializers in C# or in VB.NET.



7.2.1.2.2.1.6 Union data type

The union data type represents a (tagged) union.

> In data type dictionary model (the only model before OPC UA 1.04), union data is not directly available. A union can, however, be quite efficiently modeled using an appropriately formed structure with optional fields.

The DataFields Property contains a collection of data fields of the union data type. Each such data field is an instance of DataField Class, and specifies:

- A DataType of the contents of the field.
- A Name: Data field name, unique within the union data type.

- A Description: Human readable description of the data field.

7.2.1.2.2.2 Creating data types

You create data type objects simply by calling their constructors with appropriate arguments, and possibly filling in additional properties that were not passed into the constructors. For example:

C#

```
StructuredDataType structuredDataType = new StructuredDataType(
        "ControllerConfiguration",

"urn:UnifiedAutomation:CppDemoServer:BuildingAutomation:ControllerConfiguration")
    {
        new DataField("Name", UAOpcBinaryStandardDataTypes.CharArray),
        new DataField("DeviceAddress", UAOpcBinaryStandardDataTypes.UInt32),
        new DataField("TemperatureSetpoint", UAOpcBinaryStandardDataTypes.Double)
    };
```

Notice the use of pre-defined primitive types from the UAOpcBinaryStandardDataTypes Class. It is common to encounter references to standard data types from OPC Binary data type system, and the OPC UA Complex Data extension gives you this class so that you can refer to them easily.

7.2.1.2.2.3 Processing data types

In order to process a data type (a sub-type of DataType Class), you need to first determine its kind (see **Data type kinds (Section 7.2.1.2.2.1)**). You can do it by

- getting its Kind Property, and then having a switch or other kind of conditional statement, taking care of different data type kinds, or
- attempting to cast it (e.g. using the as operator in C#, or TryCast in VB.NET) to a concrete data type class (e.g. StructuredDataType), and testing whether it has succeeded.

There are also some common properties that all data types have, such as Name Property, FullName Property and Description Property.

After you have determined the kind of data type you are dealing with, you can use the data type object cast to appropriate type, and work with properties and methods that are specific to that data type kind. For example, a SequenceDataType contains the length of the sequence (the Length Property), and the data type of its elements (the ElementDataType Property).

The following example shows how a data type can be processed.

C#

```
// Shows how to process a data type, displaying some of its properties, recursively.

using System;
using System.Linq;
using OpcLabs.BaseLib.DataTypeModel;
```

```
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.ComplexData;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.ComplexData._DataType
{
    class Kind
    {
        public static void Main1()
        {
            // Define which server and node we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"
            UANodeDescriptor nodeDescriptor =
                "nsu=http://test.org/UA/Data/;i=10239"; //
[ObjectsFolder]/Data.Static.Scalar.StructureValue

            // Instantiate the client object.
            var client = new EasyUAClient();

            // Read a node. We know that this node returns complex data, so we can type
cast to UAGenericObject.
            UAGenericObject genericObject;
            try
            {
                genericObject = (UAGenericObject)client.ReadValue(endpointDescriptor,
nodeDescriptor);
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message);
                return;
            }
            // The data type is in the GenericData.DataType property of the
UAGenericObject.
            DataType dataType = genericObject.GenericData.DataType;

            // Process the data type. We will inspect some of its properties, and dump
them.
            ProcessDataType(dataType, maximumDepth: 2);
        }

        // Process the data type. It can be recursive in itself, so if you do not know
the data type you are dealing with,
        // it is recommended to make safeguards against infinite looping or recursion -
here, the maximumDepth.
        public static void ProcessDataType(DataType dataType, int maximumDepth)
        {
            if (maximumDepth == 0)
                return;

            Console.WriteLine();
```

```
            Console.WriteLine("dataType.Name: {0}", dataType.Name);

            switch (dataType.Kind)
            {
                case DataTypeKind.Enumeration:
                    Console.WriteLine("The data type is an enumeration.");
                    var enumerationDataType = (EnumerationDataType) dataType;
                    Console.WriteLine("It has {0} enumeration members.",
enumerationDataType.EnumerationMembers.Count);
                    Console.WriteLine("The names of the enumeration members are: {0}.",
                        String.Join(", ",
enumerationDataType.EnumerationMembers.Select(member => member.Name)));
                    // Here you can process the members, or inspect SizeInBits etc.
                    break;

                case DataTypeKind.Opaque:
                    Console.WriteLine("The data type is opaque.");
                    var opaqueDataType = (OpaqueDataType) dataType;
                    Console.WriteLine("Its size is {0} bits.",
opaqueDataType.SizeInBits);
                    // There isn't much more you can learn about an opaque data type
(well, it may have Description and
                    // other common members). It is, after all, opaque...
                    break;

                case DataTypeKind.Primitive:
                    Console.WriteLine("The data type is primitive.");
                    var primitiveDataType = (PrimitiveDataType) dataType;
                    Console.WriteLine("Its .NET value type is \"{0}\".",
primitiveDataType.ValueType);
                    // There isn't much more you can learn about the primitive data
type.
                    break;

                case DataTypeKind.Sequence:
                    Console.WriteLine("The data type is a sequence.");
                    var sequenceDataType = (SequenceDataType) dataType;
                    Console.WriteLine("Its length is {0} (-1 means that the length can
vary).", sequenceDataType.Length);

                    Console.WriteLine("A dump of the element data type follows.");
                    ProcessDataType(sequenceDataType.ElementDataType, maximumDepth -
1);
                    break;

                case DataTypeKind.Structured:
                    Console.WriteLine("The data type is structured.");
                    var structuredDataType = (StructuredDataType) dataType;
                    Console.WriteLine("It has {0} data fields.",
structuredDataType.DataFields.Count);
                    Console.WriteLine("The names of the data fields are: {0}.",
                        String.Join(", ", structuredDataType.DataFields.Select(field =>
field.Name)));

                    Console.WriteLine("A dump of each of the data fields follows.");
                    foreach (DataField dataField in structuredDataType.DataFields)
                    {
```

```
                        Console.WriteLine();
                        Console.WriteLine("dataField.Name: {0}", dataField.Name);
                        // Note that every data field also has properties like
IsLength, IsOptional, IsSwitch which might
                        // be of interest but we are not dumping them here.
                        ProcessDataType(dataField.DataType, maximumDepth - 1);
                    }
                    break;

                case DataTypeKind.Union:
                    Console.WriteLine("The data type is union.");
                    var unionDataType = (UnionDataType)dataType;
                    Console.WriteLine("It has {0} data fields.",
unionDataType.DataFields.Count);
                    Console.WriteLine("The names of the data fields are: {0}.",
                        String.Join(", ", unionDataType.DataFields.Select(field =>
field.Name)));
                    break;
            }
        }
    }
}
```

Object Pascal

```
// Shows how to process a data type, displaying some of its properties, recursively.

            End Select

        End Sub
    End Class
End Namespace
```

In many cases, you will not be processing the data type alone, but in parallel with the generic data. See **Processing generic data (Section 7.2.1.2.1.3)** for details.

7.2.1.3 OPC UA Data Type Systems

The data type system determines how the data types are described, and how the data is encoded.

In This Topic

OPC Binary data type system

This data type system uses encoding name "Default Binary" (DefaultBinary in UABrowseNames Class).

The OPC Binary data type system is defined in the OPC UA specifications. It uses XML format to describe the data types, and the data is encoded in binary form. It is the most commonly used OPC UA data type system.

The OPC UA Complex Data extension can interpret data type dictionaries in the OPC Binary data type system, and encode

and decode custom types accordingly. In addition, it contains an intrinsic knowledge of the standard data type dictionary for this data type system, as defined by the OPC Foundation. The standard data types are mapped as follows:

OPC UA standard type	Data type (DataType Class) - raw	Data type (DataType Class) - CLS compliant
http://opcfoundation.org/BinarySchema/:Bit	primitive(System.Boolean)	primitive(System.Boolean)
http://opcfoundation.org/BinarySchema/:Boolean	primitive(System.Boolean)	primitive(System.Boolean)
http://opcfoundation.org/BinarySchema/:SByte	primitive(System.SByte)	primitive(System.Int16)
http://opcfoundation.org/BinarySchema/:Byte	primitive(System.Byte)	primitive(System.Byte)
http://opcfoundation.org/BinarySchema/:Int16	primitive(System.Int16)	primitive(System.Int16)
http://opcfoundation.org/BinarySchema/:UInt16	primitive(System.UInt16)	primitive(System.Int32)
http://opcfoundation.org/BinarySchema/:Int32	primitive(System.Int32)	primitive(System.Int32)
http://opcfoundation.org/BinarySchema/:UInt32	primitive(System.UInt32)	primitive(System.Int64)
http://opcfoundation.org/BinarySchema/:Int64	primitive(System.Int64)	primitive(System.Int64)
http://opcfoundation.org/BinarySchema/:UInt64	primitive(System.UInt64)	primitive(System.Decimal)
http://opcfoundation.org/BinarySchema/:Float	primitive(System.Single)	primitive(System.Single)
http://opcfoundation.org/BinarySchema/:Double	primitive(System.Double)	primitive(System.Double)
http://opcfoundation.org/BinarySchema/:Char	primitive(System.Char)	primitive(System.Char)
http://opcfoundation.org/BinarySchema/:String	primitive(System.String)	primitive(System.String)
http://opcfoundation.org/BinarySchema/:CharArray	primitive(System.String)	primitive(System.String)
http://opcfoundation.org/BinarySchema/:WideChar	primitive(System.Char)	primitive(System.Char)
http://opcfoundation.org/BinarySchema/:WideString	primitive(System.String)	primitive(System.String)
http://opcfoundation.org/BinarySchema/:WideCharArray	primitive(System.String)	primitive(System.String)
http://opcfoundation.org/BinarySchema/:ByteString	primitive(System.Byte[])	primitive(System.Byte[])
http://opcfoundation.org/BinarySchema/:DateTime	primitive(System.DateTime)	primitive(System.DateTime)
http://opcfoundation.org/BinarySchema/:Guid	primitive(System.Guid)	primitive(System.Guid)

When the OPC Binary data type system returns primitive data provided by the server to you, it makes sure that the type of the returned is CLS-compliant, and uses the data types listed under the "CLS compliant" column. For more information, see https://docs.microsoft.com/en-us/dotnet/standard/language-independence-and-language-independent-components#Types. Most types remain unchanged during this conversion, but values of the highlighted types undergo a conversion.

When sending primitive data types from the OPC Binary data type system to the server, the OPC UA Complex Data extension will attempt to convert the value provided by the caller to the .NET type listed in the above table (under the "raw" column). This means that you can freely write e.g. System.Int32 into http://opcfoundation.org/BinarySchema/:Byte, as long as the value in the required range (0-255 for System.Byte, in this example).

Standard types defined by the OPC Foundation in the specification have their corresponding DataType Class instances in

the UAOpcBinaryStandardDataTypes Class. You can use various properties of this class to refer to standard OPC UA data types.

XML Schema data type system

This data type system uses encoding name "Default XML" (DefaultXml in UABrowseNames Class).

The OPC UA Complex Data extension currently does not support the XML Schema data type system.

7.2.1.3.1 Generic data auto-complete

> ⚠ This article only applies to the data type dictionary model, i.e. the only complex type model available before OPC UA 1.04. It does not apply to the data type definition model.

In OPC Binary data type system (see **OPC UA Data Type Systems (Section 7.2.1.3)**), there can be length fields in a structure that determine length of an array that resides in some other field of the same structure.

The OPC UA Complex Data has an auto-complete functionality which allows you, in most cases, to omit the length fields from the StructuredData you pass to the component. With this feature, the component will use the actual length of the associated SequenceData field for the value of the length field, and the length value can be omitted, or (if present) will be ignored. This allows for easier coding and also provides robustness, because the encoded data must match the value of the length field, and the encoding would be incorrect if the value of the length fields differed from the actual length of the sequence.

The value of length field will **not** be ignored if you set it to -1. This is a special value that indicates that the associated sequence should not be present in the encoded data at all. Specifying -1 for the length always causes the associated sequence be omitted (its actual length is then irrelevant).

7.2.1.4 Advanced OPC UA Complex Data Tasks

Tasks described in this chapter are usually not necessary, but they might be needed in some more advanced scenarios.

Disabling the OPC UA Complex Data extension (Section 7.2.1.4.1): For licensing or performance reasons.

Configuring the OPC UA Complex Data extension and its parts (Section 7.2.1.4.2): E.g. in order to use shared data type model provider, or to work around errors in data type dictionaries.

Navigation in the OPC UA data model (Section 7.2.1.4.3): Access metadata about data types in OPC UA.

Adding or removing data type dictionaries to or from the OPC UA data type system (Section 7.2.1.4.4): Use a data type dictionary that is different from what resides in the OPC server, or is not present in the OPC server at all

The OPC UA Complex Data extension is, well, complex. This conceptual document cannot describe all its capabilities and internal workings in full. Remember that individual types and their members are documented in the reference documentation. If you have a task that is not covered in the documentation and you are unclear about how to resolve it, contact your vendor for technical support and advice.

7.2.1.4.1 Disabling the OPC UA Complex Data extension

The OPC UA Complex Data extension is enabled by default.

Disabling the Complex Data plug-in may be useful e.g. for licensing reasons (when the product edition you have does not support the Complex Data plug-in, and you want to avoid the associated error), or for performance reasons (if you do not need the internal content of the value, for example if your code just needs to take the value read, and write it elsewhere).

Enabling or disabling the OPC UA Complex Data extension is done by settings the Enabled Property in the PluginSetup for the extension. You can locate the PluginSetup in the PluginSetups Property of the InstanceParameters of EasyUAClient. In order to find the proper PluginSetup, call the FindName Method on the PluginSetupCollection Class, giving it "UAComplexData" string as an argument, or search the PluginSetups for a PluginSetup that has its UriString Property equal to EasyUAClientUriStrings.ComplexDataPlugin.

C#

```
// Shows how to disable and enable the OPC UA Complex Data plug-in.

using System;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples.ComplexData._PluginSetup
{
    class Enabled
    {
        public static void Main1()
        {
            // Define which server and node we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"
            UANodeDescriptor nodeDescriptor =
                "nsu=http://test.org/UA/Data/;i=10239"; //
[ObjectsFolder]/Data.Static.Scalar.StructureValue

            // We will explicitly disable the Complex Data plug-in, and read a node
which returns complex data. We will
            // receive an object of type UAExtensionObject, which contains the encoded
data in its binary form. In this
            // form, the data cannot be easily further processed by your application.
            //
            // Disabling the Complex Data plug-in may be useful e.g. for licensing
reasons (when the product edition you
            // have does not support the Complex Data plug-in, and you want to avoid
the associated error), or for
            // performance reasons (if you do not need the internal content of the
value, for example if your code just
            // needs to take the value read, and write it elsewhere).

            var client1 = new EasyUAClient();
            client1.InstanceParameters.PluginSetups.FindName("UAComplexData").Enabled =
```

```
false;

            object value1;
            try
            {
                value1 = client1.ReadValue(endpointDescriptor, nodeDescriptor);
            }
            catch (UAException uaException)
            {
                Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message);
                return;
            }
            Console.WriteLine(value1);

            // Now we will read the same value, but with the Complex Data plug-in
enabled. This time we will receive an
            // object of type UAGenericObject, which contains the data in the decoded
form, accessible for further
            // processing by your application.
            //
            // Note that it is not necessary to explicitly enable the Complex Data
plug-in like this, because it is enabled
            // by default.

            var client2 = new EasyUAClient();
            client2.InstanceParameters.PluginSetups.FindName("UAComplexData").Enabled =
true;

            object value2 = client2.ReadValue(endpointDescriptor, nodeDescriptor);
            Console.WriteLine(value2);

            // Example output:
            //
            // Binary Byte[1373]; {nsu=http://test.org/UA/Data/;i=11437}
            // (ScalarValueDataType) structured

            // On the first line, the type and length of the encoded data is shown, and
the node ID is the encoding ID.
            // On the 2nd line, the kind (structured) and the name of the complex data
type (ScalarValueDataType) is shown.
        }
    }
}

When the OPC UA Complex Data extension is disabled, the component

- returns instances of UAExtensionObject Class when nodes with complex data are read or subscribed to,
- expects instances of UAExtensionObject Class when nodes with complex data are written to,
- does not allow you to obtain services related to OPC UA Complex Data (such as IEasyUAClientComplexData Interface from the instance of the EasyUAClient Class using the GetService Method.

When the OPC UA Complex Data extension is enabled (the default) but the current license does not allow the OPC UA Complex Data feature, reads, subscriptions and writes, or attempts to obtain services related to OPC UA Complex Data,

will return an error.

> ⚠ Enabling or disabling the extension only has effect when done before you attempt first OPC operation or GetService Method call on the object instance.

7.2.1.4.2 Configuring the OPC UA Complex Data extension and its parts

There are various parameters that can be configured on the OPC UA Complex Data extension. Take following steps to read or modify them:

1. Access the InstanceParameters Property of your EasyUAClient Class instance.
2. In the InstanceParameters Property, access the PluginConfigurations Property.
3. Call the Find Method of the ConfigurationPartCollection Class, passing it the name of the type of the configuration part you want to modify. The available type names and their purposes are listed further below.
4. Read or modify the properties of the obtained object as needed.

Some typical scenarios for which the configuration might be needed are described below.

> ⚠ Configuring the extension only has effect when done before you attempt first OPC operation or GetService Method call on the object instance.

In This Topic

Using shared data type model provider

The data type model provider (DTMP) is an object that provides access to the metadata about data type in the target OPC server(s). The data type model provider also caches the metadata obtained, so that repeated decodings of the same data types do not require retrieving the metadata from the OPC server(s) again and again.

By default, each instance of the EasyUAClient Class has its own data type model provider. If you use multiple instances of the EasyUAClient Class and do not require them be fully isolated in this respect, you should consider switching to a shared data type model provider.

Conceptually, there is no noticeable difference in the results from the default state in which the client objects are set to use per-instance data type model provider. But, with the shared data type model provider, the metadata obtained during the operations on one client object and cached inside the data type model provider are reused during operations on other client objects, making this and the subsequent operations more efficient.

The configuration part that you need to access is the UAComplexDataPluginParameters Class.

Configuring data type dictionary locations

In OPC Binary data type system, data type dictionaries that reside in the OPC server may use types from other data type dictionaries, and optionally specify location of these other dictionaries, using a string. The OPC UA specification does not define a format for such string.

The OPC UA Complex Data extension already contains data the standard data type dictionary defined in the OPC UA specification, and some others. It also knows how to resolve their namespaces to locations, therefore (by default), the data type dictionaries in the server do not have to specify the location for them.

For other namespaces, the OPC Binary data type system recognizes following syntax for the location string:

- If the string can be parsed as an OPC UA Node ID with explicitly specified namespace (by URI or namespace index), it is understood to be a reference to a node in the same OPC server, and resolved as such.
- Otherwise, the location string is understood to be a URI.

If the location string is understood to be a URI, it can be only:

- A URI with special "net.res" URI scheme, referring to a managed (.NET) resource embedded in some .NET assembly. The syntax of this URI is "net.res://*assemblyName/resourceName*".
- A file URI, or a universal naming convention (UNC) path.

For import directives that do not have their location string specified, the OPC Binary data type system tries to find the location in the WellKnownLocationTemplateDictionary Property. You can therefore access the UAOpcBinaryDtsParameters Class configuration part, and add your entry (entries) to this dictionary, in order to tell the OPC Binary data type system where to find the data type dictionaries. You can specify a node ID in the server if the data type dictionary resides there, or place the data type dictionary into a file, or embed it in a managed resource in your program.

Working around errors in data type dictionaries

The OPC UA Complex Data is commonly implemented with some bugs on the server side. In addition, at time of writing this article, it is not rigorously (or at all) checked during OPC compliance certification process, and only to very limited extent during OPC Interoperability Workshops. The client must therefore be prepared to handle situations in which the server behavior is erroneous.

We have tested the OPC UA Complex Data extension against several servers with complex data support available, and continue to expand the range of interoperable servers. We have found several issues in these servers (and in the OPC UA specifications) during these tests, and have already provided special coding and configuration inside the OPC UA Complex Data extension to work around these issues.

If you encounter a buggy server and the workaround is not already built into the OPC UA Complex Data extension, you might be able to work around the problem by configuring the extension accordingly. You are also welcome to report the problem to us, so that we can adjust the software and prevent the issue in future versions.

For errors related to the OPC Binary data type system, the configuration part you need to access is the UAOpcBinaryDtsParameters Class.

Here are some common issues with OPC Binary data type system, and their possible workarounds:

- The data type dictionary uses some external types, but fails to list the namespace (and possibly location) in the import directives. To rectify this, add the import directive to ImplicitImportDictionary Property.
- The data type dictionary uses incorrect (e.g. misspelled) namespace in some of its type references. To rectify this, redirect the namespace by adding an entry to the NamespaceRedirectionDictionary Property.
- The data type dictionary uses some incorrect (e.g. misspelled) type name, or the type name is correct but the type definition in the dictionary does not match the actual encoding used "on the wire". To rectify this, add an appropriate entry to TypeNameRemappingDictionary Property.

7.2.1.4.3 Navigation in the OPC UA data model

For accessing the metadata about data types in OPC UA and navigating in it, the OPC UA Complex Data extension gives you

- An OPC UA data type model provider (DTMP) , represented by the IUADataTypeModelProvider Interface.
- An OPC UA data type dictionary provider, represented by the IUADataTypeDictionaryProvider Interface, and used with the data type dictionary model (the only complex data model available before OPC UA 1.04).
- An OPC UA data type definition provider, represented by the IUADataTypeDefinitionProvider Interface, and used with the data type definition model (the complex data model available since OPC UA 1.04).

The providers retrieve the information from the OPC server in various ways (by reading and browsing the metadata nodes). In addition, they cache the information obtained. This is very important for performance reasons, because the same metadata can be reused without having to retrieve them from the server again and again.

In This Topic

OPC UA data type model provider

Take following steps to get access to the OPC UA data type model provider:

1. Get the IEasyUAClientComplexData Interface service from your EasyUAClient Class instance using the GetService Method.
2. Using the DataTypeModelProvider Property, obtain the IUADataTypeModelProvider Interface.

When you have the IUADataTypeModelProvider Interface, you can call its methods to:

- Get data type IDs from given data type encoding IDs (GetDataTypeIdsFromDataTypeEncodingIds Method).
- Get data type IDs from given model node descriptors (GetDataTypeIdsFromModelNodeDescriptors Method).
- Get encoding node element collections from given data type IDs (GetEncodingNodeElementCollectionsFromDataTypeIds Method).

The basic methods on the IUADataTypeModelProvider Interface provide just one navigation "hop" at a time. Some of these "hops" are, however, commonly needed together, in a chain, possibly with some kind of additional simple processing. For this purpose, there are extension methods available (in

the IUADataTypeModelProviderExtension Class) that make such tasks easier. With help of these methods, you can then, for example:

- Resolve encoding IDs from given data type IDs and an encoding name.
- Resolve encoding IDs from given model node descriptors and an encoding name.

If you have more pieces of information to work on in the same way, it is much more efficient to process them together, in one operation. All methods on the IUADataTypeModelProvider Interface and the IUADataTypeModelProviderExtension Class therefore accept a read-only list on input, and return an array of processed element on the output. If performance is not a concern, or if you have just one piece of information to work on at a time, there are extension methods to make it easier as well. For example, instead of calling GetDataTypeIdsFromModelNodeDescriptors Method for just one node, you can use the GetDataTypeIdFromModelNodeDescriptor Method instead.

OPC UA data type dictionary provider

> ⚠ This chapter only applies to the data type dictionary model, i.e. the only complex type model available before OPC UA 1.04. It does not apply to the data type definition model.

Take following steps to get access to the OPC UA data type dictionary provider:

1. Get the IEasyUAClientComplexData Interface service from your EasyUAClient Class instance using the GetService Method.
2. Using the DataTypeDictionaryProvider Property, obtain the IUADataTypeDictionaryProvider Interface.

When you have the IUADataTypeDictionaryProvider Interface, you can call its methods to:

- Get data type description IDs from given data type encoding IDs (GetDataTypeDescriptionIdsFromDataTypeEncodingIds Method).
- Get data type descriptions from given data type description IDs (GetDataTypeDescriptionsFromDataTypeDescriptionIds Method).
- Get data type dictionaries from given data type dictionary IDs (GetDataTypeDictionariesFromDataTypeDictionaryIds Method).
- Get data type dictionary IDs from given data type description IDs (GetDataTypeDictionaryIdsFromDataTypeDescriptionIds Method).

The basic methods on the IUADataTypeDictionaryProvider Interface provide just one navigation "hop" at a time. Some of these "hops" are, however, commonly needed together, in a chain, possibly with some kind of additional simple processing. For this purpose, there are extension methods available (in the IUADataTypeDictionaryProviderExtension Class) that make such tasks easier. With help of these methods, you can then, for example:

- Resolve data type descriptors from given data type encoding IDs.

If you have more pieces of information to work on in the same way, it is much more efficient to process them together, in one operation. All methods on the IUADataTypeDictionaryProvider Interface and the IUADataTypeDictionaryProviderExtension Class therefore accept a read-only list on input, and return an array of processed element on the output. If performance is not a concern, or if you have just one piece of information to work on at a time, there are extension methods to make it easier as well.

OPC UA data type definition provider

> ⚠ This chapter only applies to the data type definition model, i.e. the complex type model available since OPC UA 1.04. It does not apply to the data type description model.

Take following steps to get access to the OPC UA data type dictionary provider:

1. Get the IEasyUAClientComplexData Interface service from your EasyUAClient Class instance using the GetService Method.
2. Using the DataTypeDefinitionProvider Property, obtain the IUADataTypeDefinitionProvider Interface.

When you have the IUADataTypeDefinitionProvider Interface, you can call its methods to:

- Get data type infos from given data type IDs (GetDataTypeInfosFromDataTypeIds Method). The data type info is represented by an instance of the UADataTypeInfo Class, and provides metadata for the OPC UA custom data type in the data type definition model.

If you have more pieces of information to work on in the same way, it is much more efficient to process them together, in one operation. All methods on the IUADataTypeDictionaryProvider Interface therefore accept a read-only list on input, and return an array of processed element on the output. If performance is not a concern, or if you have just one piece of information to work on at a time, there are extension methods in the IUADataTypeDefinitionProviderExtension Class to make it easier as well.

Resolving the data type

When you receive complex data in the GenericData Property of a UAGenericObject, it has its DataType Property filled in with information about the associated data type, so that you can process it as you need. But what you have not yet received the complex data from the server - maybe you are just preparing something to be written, and you want to inspect what is the data type structure for certain node or data type ID? In this case, you can use the

methods on the IUADataTypeModelProvider Interface to obtain an instance of DataType Class.

The example below shows how to resolve a data type. The main work is done by the ResolveDataType Method.

C#

```
// Shows how to obtain object describing the data type of complex data node with OPC UA Complex Data plug-in.

using System;
using OpcLabs.BaseLib.DataTypeModel;
using OpcLabs.BaseLib.Extensions;
using OpcLabs.BaseLib.OperationModel.Generic;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.InformationModel;
using OpcLabs.EasyOpc.UA.Plugins.ComplexData;

namespace UADocExamples.ComplexData._IEasyUAClientComplexData
{
    class ResolveDataType
    {
        public static void Main1()
        {
            // Define which server we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object.
            var client = new EasyUAClient();

            // Obtain the data type ID.
            //
            // In many cases, you would be able to obtain the data type ID of a particular node by reading its
DataType
            // attribute, or easier, by calling the extension method ReadDataType on the IEasyUAClient interface.
            // The sample server, however, shows a more advanced approach in which the data type ID refers to an
abstract
            // data type, and the actual values are then sub-types of this base data type. This abstract data
type does not
            // have any encodings associated with it and it is therefore not possible to extract its description
from the
            // server. We therefore use a hard-coded data type ID for one of the sub-types in this example.
            //
            // The code to obtain the data type ID for given node would normally look like this:
            //    UANodeId dataTypeId = client.ReadDataType(
            //        endpointDescriptor,
            //        "nsu=http://test.org/UA/Data/;i=10239");    //
[ObjectsFolder]/Data.Static.Scalar.StructureValue
            //
            UANodeId dataTypeId = "nsu=http://test.org/UA/Data/;i=9440";    // ScalarValueDataType

            // Get the IEasyUAClientComplexData service from the client. This is needed for advanced complex data
            // operations.
            IEasyUAClientComplexData complexData = client.GetService<IEasyUAClientComplexData>();

            // Resolve the data type ID to the data type object, containing description of the data type.
            ValueResult<DataType> dataTypeResult = complexData.ResolveDataType(
                new UAModelNodeDescriptor(endpointDescriptor, dataTypeId),
                UABrowseNames.DefaultBinary);
            // Check if the operation succeeded. Use the ThrowIfFailed method instead if you want exception be
thrown.
            if (!dataTypeResult.Succeeded)
            {
                Console.WriteLine("*** Failure: {0}", dataTypeResult.ErrorMessageBrief);
                return;
            }

            // The actual data type is in the Value property.
            // Display basic information about what we have obtained.
            Console.WriteLine(dataTypeResult.Value);
```

```
            // If we want to see the whole hierarchy of the received data type, we can format it with the "V"
(verbose)
            // specifier. In the debugger, you can view the same by displaying the private DebugView property.
            Console.WriteLine();
            Console.WriteLine("{0:V}", dataTypeResult.Value);

            // For processing the internals of the data type, refer to examples for GenericData class.

            // Example output (truncated):

Obtaining content of the data type dictionary

You may sometimes need to view the actual content of the data type dictionary that resides in the OPC server. In itself, this is easy: The data type dictionary is in a node, so you just read the node. But, how do you find out which node to read? Here is where the IUADataTypeModelProvider Interface or the IUADataTypeDictionaryProvider Interface can help. They have methods to navigate from the node you want to access (read, write, or subscribe to) to the data type dictionary. Or, they have similar methods if you know the data type ID of the data type you are interested in. The example below shows the steps necessary.

C#

```
// Shows how to obtain data type description object for complex data node with OPC UA Complex Data plug-in, and
the actual
// content of the data type dictionary.

using System;
using System.Text;
using OpcLabs.BaseLib.Extensions;
using OpcLabs.BaseLib.OperationModel.Generic;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.DataTypeModel;
using OpcLabs.EasyOpc.UA.DataTypeModel.Extensions;
using OpcLabs.EasyOpc.UA.InformationModel;
using OpcLabs.EasyOpc.UA.Plugins.ComplexData;

namespace UADocExamples.ComplexData._IUADataTypeDictionaryProvider
{
    class ResolveDataTypeDescriptorFromDataTypeEncodingId
    {
        public static void Main1()
        {
            // Define which server we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object.
            var client = new EasyUAClient();

            // Obtain the data type ID.
            //
            // In many cases, you would be able to obtain the data type ID of a particular node by reading its
DataType
            // attribute, or easier, by calling the extension method ReadDataType on the IEasyUAClient interface.
The sample
            // server, however, shows a more advanced approach in which the data type ID refers to an abstract
data type,
            // and the actual values are then sub-types of this base data type. This abstract data type does not
have any
            // encodings associated with it and it is therefore not possible to extract its description from the
server.
            // We therefore use a hard-coded data type ID for one of the sub-types in this example.
            //
            // The code to obtain the data type ID for given node would normally look like this:
            //    UANodeId dataTypeId = client.ReadDataType(
            //        endpointUriString,
            //        "nsu=http://test.org/UA/Data/;i=10239");    //
[ObjectsFolder]/Data.Static.Scalar.StructureValue
            //
            UANodeId dataTypeId = "nsu=http://test.org/UA/Data/;i=9440";    // ScalarValueDataType

            // Get the IEasyUAClientComplexData service from the client. This is needed for advanced complex data
            // operations.
            IEasyUAClientComplexData complexData = client.GetService<IEasyUAClientComplexData>();
```

```

```

7.2.1.4.4 Adding or removing data type dictionaries to or from the OPC UA data type system

In some cases, you may want the component to use a data type dictionary that is different from what resides in the OPC server, or is not present in the OPC server at all. These situations may be, for example:

- The server vendor has intentionally omitted the data type dictionary from the OPC server due to performance and size constraints (small embedded devices).
- The server vendor has omitted the data type dictionary from the OPC server due to mistake or overlook.
- The OPC server contains the data type dictionary, but the dictionary does not match the actual data types and encoding.

Each data type dictionary is identified by the endpoint descriptor and node descriptor (data type dictionary ID) in the data type system. You can externally add or remove data type dictionaries from your code, identifying them by the data type dictionary ID.

Take following steps to add or remove the data type dictionary:

1. Get the IEasyUAClientComplexData Interface service from your EasyUAClient Class instance using the GetService Method.
2. Using the FindDataTypeSystem Method on the IEasyUAClientComplexData Interface, find the data type system you

want to manipulate. Pass in the encoding name of the data type system, e.g. DefaultBinary Property.
3. Call the AddDataTypeDictionary Method or the RemoveDataTypeDictionary Method on the IUADataTypeSystem Interface.

Note that the data type system may only contain data type dictionaries that were previously referenced. Once the data type dictionary is added, be it from your code or otherwise, it stays there until removed. If your intent is to re-define an existing data type dictionary or define a data type dictionary that does not exist in the server, you need to add it to the data type system at the beginning, before an attempt tor etrieve it from the server is made.

8 Application Deployment

This chapter describes how to deploy applications developed with use of OPC Data Client.

For some uses, it is acceptable to perform the deployment manually. In other cases, you will find yourself writing an installer for your application, and you will probably want to include the installation of OPC Data Client components in it as well. On Windows, Production installer (part of OPC Data Client) can help with that.

8.1 Deployment Methods

You can deploy your application with OPC Data Client using following methods:

1. **Manual Deployment (Section 8.1.1)**: Doing the necessary deployment steps manually. On Windows and when not targeting the .NET Standard, the OPC Data Client installer can be used to help with initial parts of the manual process.
2. **Automated deployment, roll your own (Section 8.1.2)**: By writing your an installer for your application, and including in it the steps needed to deploy the individual OPC Data Client elements.
3. **Automated deployment with Production installer (Section 8.1.3)** (Windows only; not when targeting .NET Standard): By writing an installer for your application, and having your installer embed and invoke the OPC Data Client Production installer.

8.1.1 Manual Deployment

.NET Framework, COM and Excel Development

In order to deploy your .NET Framework, COM or Excel application with OPC Data Client on Windows manually, follow the steps below:

1. Check that proper version of Microsoft .NET Framework is installed, and if it is not, install it. See **.NET Runtimes (Section 2.4.1)** for details.
2. Run the OPC Data Client Full installation program, selecting “Custom install” choice and later “Production installation” type. Alternatively, run the OPC Data Client Production installer instead. The main purpose of this step is to obtain the set of OPC Data Client assemblies; if you have them available by other means, you can skip this step.
3. a. Copy the OPC Data Client assemblies to their target locations for your application.
   b. If you are developing on a COM platform, perform additional actions (such as the assembly registrations) as described with the respective files in **Installing COM Components and Type Libraries (Section 8.3.2)** . This might have been performed by the installer in Step 2 above, but needs to be re-done if you have moved the assemblies from their original locations.
4. Perform any steps needed to install your own application.
5. If you are using a license located in the **Registry License Store (Section 8.5.2)**, run the License Manager from the Start menu or the Launcher application, and install the runtime license. Alternative, use command line and the LMConsole utility for this.
6. With OPC Data Client-UA only: Run your application once with the administrative privileges, giving it a chance to

In This Topic

create its client instance certificate (this step is only needed if you do not provide the client instance certificate in some other way).

.NET Standard Development

In .NET Standard, manual deployment steps are more or less indistinguishable from what is considered as creating an "automated deployment". For this reason, refer to **Automated deployment, roll your own (Section 8.1.2)** for the deployment steps.

8.1.2 Automated deployment, roll your own

.NET Framework, COM and Excel Development

Using this method, you write an installer for your application, and include an installation of OPC Data Client elements in it as well, step by step.

The installer for your application should contain following steps:

1. Check that prerequisites (in their proper versions), are installed, and if they are not, instruct the user to install them (or install them automatically).
2. Install OPC Data Client.NET and/or OPC Data Client-UA assemblies to their target locations for your application.
3. For OPC Data Client-COM and OPC Data Client-UA for COM, perform additional actions (such as the assembly registrations) as described with the respective files in **Installing COM Components and Type Libraries (Section 8.3.2)**.
4. Perform any steps needed to install your own application.
5. With OPC Data Client-UA only: While running with administrative privileges, execute your application with a special command-line switch that will cause it to call static EasyUAClient**.**Install method. This will create the client instance certificate, in accordance with settings of other static properties on the object (this step is only needed if you do not provide the client instance certificate in some other way). For more information, see **Providing OPC UA Client Instance Certificate (Section 4.13.1.1)** and **OPC UA Certificate Stores (Section 4.13.1.4)**.
6. If you are using a license located in the **Registry License Store (Section 8.5.2)**, take care of the license installation (this is described further down).

If you want the end user to install the license:

1. Install LicenseManager.exe or LMConsole.exe (from Bin or Bin\x64).
2. Create an empty registry key **HKEY_LOCAL_MACHINE\SOFTWARE\Licensing\QuickOPC**
3. Offer the user an option to run the License Manager.

The end user who deploys the application will then:

1. Run your installer and follow the steps.
2. Use the License Manager (GUI or console-based) and install the runtime license.

If the above described procedure for installing the license (presenting the user with the License Manager utility user interface) does not fit the needs of your application, you can automate the deployment of the license as well. This can be done in two ways:

a. Directly - by writing information into the license store. For more information, see Direct License Deployment.
b. By using the **LMConsole Utility (License Manager Console) (Section 11.1.1)**. Your installer will (at least temporarily) place the LMConsole.exe and the actual license file on the disk, and then call the LMConsole utility with corresponding parameters on the command line.

The **LicenseManager** (GUI-based) and **LMConsole** (console-based) License Manager utilities are installed on the disk using the OPC Data Client-s **Setup** program.

.NET Standard Development

In .NET Standard, the major installation element is not an assembly, but rather a (NuGet) package, which may consist of multiple assemblies, differentiated by the target platform, and may depend on other packages.

The OPC Data Client license needs to be stored inside your aplication in the **Managed Resource License Store (Section 8.5.1)** (the **Registry License Store (Section 8.5.2)** is not supported in .NET Standard). Consequently, there are no additional deployment elements or steps needed with regard to licensing, because the license key is already embedded in your project's assembly by the build process.

With OPC Data Client-UA only: After deploying the assemblies, your installation may want to execute your application with a special switch that will cause it to call static EasyUAClient.Install method. This will create the client instance certificate, in accordance with settings of other static properties on the object. With the default settings, this step is optional, and the application will create the client instance certificate on the first run anyway. If you, however, change the location of the application certificate store to a store that requires administrative privileges for write access, you should use this approach (while running with administrative privileges) in order to assure that the client instance certificate is properly created. For more information, see **Providing OPC UA Client Instance Certificate (Section 4.13.1.1)** and **OPC UA Certificate Stores (Section 4.13.1.4)**.

.NET Core

In order to deploy your application developed with OPC Data Client for the .NET Core runtime (on Windows, Linux, or other operating system if supported), you can use either:

- **Framework-dependent Deployment (FDD)**, or
- **Self-contained Deployment (SCD)**.

Both these deployment types are described in Microsoft's article .NET Core application deployment. OPC Data Client does not have any special requirements or procedures needed above that.

8.1.3 Automated deployment with Production installer

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

In This Topic

The OPC Data Client contains a separate installation package (for Windows) that is for

production purposes only. This installer executable has a "-Production" postfix. It is much smaller than the Full installer: At the time of writing this article, the full installer has 90 MB, while the production installer has only 10 MB. The production installer contains only the assemblies and the LMConsole utility (for licensing), and a code to optionally register the assemblies as COM components, and/or produce the type libraries (TLB) for them. The production installer does not install any Start menu icons. It is intended for embedding in other installation programs. It can be automated from the command line, and can also be run silently.

The developer will find the link to download the production installer in the Redist directory.

The production installer is created using Inno Setup. This means that if you want to automate it from your own installer using command line, you can use all Setup Command Line Parameters it provides, and check Setup Exit Codes as needed. You will typically use the **/SILENT** or **/VERYSILENT** parameter, possibly combined with **/TYPE**, **/COMPONENTS**, **/TASKS** or **/MERGETASKS** parameters.

Setup Types

The available setup types (for the **/TYPE=*type name*** parameter) are:

Setup Type Name	Description
production	Production installation
productionnet	Production installation (.NET only)
productioncom	Production installation (COM only)
productionexcel	Production installation (Excel only)
custom	Custom installation

Setup Components

If you need more control over the installed parts, you can specify the components to be installed individually. The available components (for the **/COMPONENTS="*comma separated list of component names*"** parameter) are:

Component Name	Description
assemblies	Assemblies
assemblies\embedded	Embedded assemblies
comcomponents	COM Components
typelibs	Type Libraries (COM)
tools\productiontools	Production Tools (License Manager, ...)
options\excel	Excel Option
options\streaminsight	StreamInsight Option

The License Manager component in the Production installer contains only the console-based license manager

(LMConsole.exe), and not the GUI.

Setup Tasks

You can also instruct the Setup to perform additional tasks during installation, using **/TASKS** in the command line. The available tasks are:

Task Name	Description
installtogac	Install component assemblies into the GAC. This is normally neither necessary nor recommended.

License Install

The production installer can be passed an additional command line parameter ("**/LicenseFile=...**") with a path to the license key file (typically with .BIN or .TXT extension), causing it to automatically install the license as part of the setup process.

If you have two license files to install (with some of the **Product Options (Section 12)**), use "**/LicenseFile2=...**" to install the second license file.

⚠ Unless you specify a path in the file name, the file is assumed to be in the same directory as the installer's executable. It is recommended to use a full path in the file name to avoid ambiguity and assure correct installation of the license.

Uninstallation

It is also possible to automate the uninstallation. For that, the production installer places a unins000.exe file in the Setup directory of the product folder, where your own uninstaller can find it and call it as well. More information to this you will find in Uninstaller Command Line Parameters and Uninstaller Exit Codes.

The Production installer does not configure the software. For example, if you need the Connectivity RTD Server to use a specific connectivity configuration, you need to install the **ConnectivityConfiguration2.xml** file yourself.

8.2 Deployment Prerequisites

.NET Framework, COM and Excel Development

Besides the actual library assemblies, QuickOPC requires that the software described below is present on the target system.

.NET Framework - you need (at least) one of the following:

- .NET Framework 4.7
- .NET Framework 4.7.1
- .NET Framework 4.7.2
- .NET Framework 4.8

In This Topic

Note that

- .NET Framework 4.7 is included with Windows 10 version 1703 (Creators Update).
- .NET Framework 4.7.1 is included with Windows 10 version 1709 (Fall Creators update).
- .NET Framework 4.7.2 is included with Windows 10 version 1803 (April 2018 Update), version 1809 (October 2018 Update), Windows Server versions 1803 and 1809, and Windows Server 2019.
- .NET Framework 4.8 is included with Windows 10 version 1903 (May 2019 Update).

In some special cases, you may want to install other prerequisites – please refer to **Prerequisites Boxing (Section 9.12)** under **Advanced Topics (Section 9)**.

.NET Standard Development

.NET Core

If you are using a **framework-dependent deployment (FDD)**, it is necessary that proper version of .NET Core is installed on the target system. If you are using a **self-contained deployment (SCD)**, there are usually no deployment prerequisites other than using a supported operating system and hardware.

See **.NET Runtimes (Section 2.4.1)** for more information about the support .NET Core versions and **Operating Systems (Section 2.4.2)**. For more information about deployment types in .NET Core, see the Microsoft's article .NET Core application deployment.

8.3 Installation Elements

The elements described in this chapter need to be installed with your application based on OPC Data Client.

8.3.1 Installing Assemblies (.NET)

.NET Framework, COM and Excel Development

Depending on which assemblies you have referenced in your application, you may need one or more of the following files be installed with your application:

- App_Web_OpcLabs.EasyOpcClassicRaw.amd64.dll
- App_Web_OpcLabs.EasyOpcClassicRaw.x86.dll
- OpcLabs.BaseLib.dll
- OpcLabs.BaseLibForms.dll
- OpcLabs.BaseLibPresentation.dll
- OpcLabs.EasyOpcClassic.dll
- OpcLabs.EasyOpcForms.dll
- OpcLabs.EasyOpcUA.dll

Please refer to “Product Parts” chapter for description of purpose of individual assemblies. You will find them under the Assemblies\net47 subdirectory in the installation directory of the product.

In This Topic

The assemblies need to be placed so that the referencing software (your application) can find them, according to standard Microsoft .NET loader (Fusion) rules. The easiest is to simply place the assembly files alongside (in the same directory as) your application file.

There are other methods of how assemblies can be located, including their installation to GAC (Global Assembly Cache). Which method you use depends on the needs of your application. Unless you have a compelling need, however, we do not recommended installing the assemblies into the GAC.

.NET Standard Development

Remember that in .NET Standard, the deployment will contain not only the files of your application and OPC Data Client files, but also the files from NuGet packages that OPC Data Client depends on, and that you have to comply with their licensing requirements as well.

.NET Core

In .NET Core, the assemblies that become the part of the deployment are determined and included automatically by the tools that build the deployment. For more information, see Microsoft's article .NET Core application deployment.

OpcLabs.Pcap and its dependencies

If your application needs to use OPC UA PubSub Ethernet mapping, or it needs to work with Wireshark capture files, you also need to install:

- OpcLabs.Pcap.dll
- PacketDotNet.dll
- SharpPcap.dll

In addition, you need to comply with LGPL requirements of PacketDotNet and SharpPcap.

8.3.2 Installing COM Components and Type Libraries

Because OPC Data Client-COM and OPC Data Client-UA for COM are implemented by exposing the .NET objects of OPC Data Client to COM, you need to basically do two things:

1. Deploy the assemblies needed for .NET (see preceding chapter).
2. Register them using the Assembly Registration tool (**Regasm.exe**)

The Assembly Registration tool is a part of .NET Framework, and is therefore available on every computer that has the .NET Framework installed. You only need to apply the Assembly Registration tool to the following assemblies:

- OpcLabs.BaseLib.dll
- OpcLabs.BaseLibForms.dll
- OpcLabs.EasyOpcClassic.dll
- OpcLabs.EasyOpcForms.dll
- OpcLabs.EasyOpcUA.dll

For more information, please refer to http://msdn.microsoft.com/en-us/library/tzat5yw6(v=vs.110).aspx. It is recommended that you use the **/codebaseoption** when registering the assemblies.

⚠ On 64-bit systems, a 32-bit and a 64-bit version of **RegAsm.exe** are present. Using the 32-bit version of **RegAsm.exe** registers the assembly for use by 32-bit COM applications, and using the 64-bit of **RegAsm.exe** registers the assembly for use by 64-bit COM applications. Depending on your needs, you need to select the proper version of **RegAsm.exe**, or even use them both.

8.4 Configuration Elements

There are currently no configuration elements for OPC Data Client deployments.

8.5 Licensing Elements

License Location

In This Topic

The OPC Data Client license is located in a *license store*. The following table lists the license stores available under each development platform, and their search order.

Search Order	License Store Type	COM	.NET Framework	.NET Standard (new in 2018.3)	Excel (with Excel Option (Section 12.1))
1.	**Managed Resource License Store (Section 8.5.1)** (new in 2018.3)	×	✓	✓	×
2.	**Registry License Store (Section 8.5.2)**	✓	✓	×	✓
3.	Built-in License Store (trial license only)	✓	✓	✓	✓

OPC Data Client attempts to find a valid license in the available license stores, using a pre-set search order as given above (from top to bottom). If a valid license is found, it is used. If it is not found, the search proceeds to the next available license store. There is always a valid trial license available in the Built-in License Store. This is the one that will be used if everything else fails.

The **Managed Resource License Store (Section 8.5.1)** allows you to embed the license directly within your application (in a .NET assembly). This method cannot be used on the COM platform. Its advantage is that it does not require any further actions during deployment.

With the **Registry License Store (Section 8.5.2)**, proper license (for runtime usage) must be installed on the target computer (the computer where the product will be running). The **License Manager** utility (GUI or console-based) is normally needed for this. The GUI-based **License Manager** is contained in the **LicenseManager.exe** file. The console-based License Manager is contained in the **LMConsole.exe** file. Both files are located under the **Bin** subdirectory of the product. Alternatively, you can write an installation program that installs the license into the **Registry License Store (Section 8.5.2)** automatically. The **Registry License Store (Section 8.5.2)** is not available on the .NET Standard

development development platform.

> ⚠ The fact that you have used a valid OPC Data Client license in the **Registry License Store (Section 8.5.2)** during development and building of your application does not mean that the resulting application will automatically be licensed on a different computer. You must do the extra steps described in this documentation (depending on the license store chosen) in order to assure that your deployed application is licensed in runtime.

License Verification

If the proper license is not installed, you will end up with the trial license being used instead, as described above. That is usually manifested by the fact that after 30 minutes of the process run time, the component stops delivering valid data and gives an error instead.

Of course, you might want to know and verify sooner whether the license you intended to use has been found, validated and used. You can do so from your program by inspecting the elements of the dictionary returned from the LicenseInfo Property on the EasyXXClient object. The dictionary is keyed by strings, and you can obtain various information related to the license from it. If you simply want to verify that the right license is in use, we suggest that you test its serial number, either by excluding a range for demo and trial licenses (as in the following example), or by requiring that the serial number of the license in use is equal to the precise serial number of your license. You obtain the serial number by getting the **"Multipurpose.SerialNumber"** element of the dictionary. The license key file you obtained when you purchased OPC Data Client has your serial number as its first series of digits.

The example below shows how to obtain the serial number of the active license, and determine whether it is a demo or trial license.

C#

```
// Shows how to obtain the serial number of the active license, and determine whether
it is a stock demo or trial license.

using System;
using OpcLabs.EasyOpc.UA;

namespace UADocExamples.Licensing
{
    class LicenseInfo
    {
        public static void SerialNumber()
        {
            // Instantiate the client object.
            var client = new EasyUAClient();

            // Obtain the serial number from the license info.
            long serialNumber = (uint)client.LicenseInfo["Multipurpose.SerialNumber"];

            // Display the serial number.
            Console.WriteLine("SerialNumber: {0}", serialNumber);

            // Determine whether we are running as demo or trial.
            if ((1111110000 <= serialNumber) && (serialNumber <= 1111119999))
                Console.WriteLine("This is a stock demo or trial license.");
            else
                Console.WriteLine("This is not a stock demo or trial license.");
```

```
        }
    }
}
```

Object Pascal

```
// Shows how to obtain the serial number of the active license, and determine whether
it is a stock demo or trial license.

class procedure LicenseInfo.SerialNumber;
var
  Client: _EasyUAClient;
  SerialNumber: Int64;
begin
  // Instantiate the client object
  Client := CoEasyUAClient.Create;

  // Obtain the serial number from the license info.
  SerialNumber := Int64(client.LicenseInfo['Multipurpose.SerialNumber']);

  // Display the serial number.
  WriteLn('SerialNumber: ', SerialNumber);

  // Determine whether we are running as demo or trial.
  if ((1111110000 <= SerialNumber) and (SerialNumber <= 1111119999)) then
    WriteLn('This is a stock demo or trial license.')
  else
    WriteLn('This is not a stock demo or trial license.');
end;
```

PHP

```
// This example shows how to obtain nodes under a given node of the OPC-UA address
space.
// Shows how to obtain the serial number of the active license, and determine whether
it is a stock demo or trial license.

// Instantiate the client object
$Client = new COM("OpcLabs.EasyOpc.UA.EasyUAClient");

// Obtain the serial number from the license info.
$SerialNumber = $Client->LicenseInfo["Multipurpose.SerialNumber"];

// Display the serial number.
printf("SerialNumber: %s\n", $SerialNumber);

// Determine whether we are running as demo or trial.
if ((1111110000 <= $SerialNumber) and ($SerialNumber <= 1111119999))
    printf("This is a stock demo or trial license.\n");
  else
    printf("This is not a stock demo or trial license.\n");
```

VB.NET

```
' Shows how to obtain the serial number of the active license, and determine whether it
is a stock demo or trial license.
```

```
Imports OpcLabs.EasyOpc.UA

Namespace UADocExamples.Licensing
    Friend Class LicenseInfo
        Public Shared Sub SerialNumber()

            ' Instantiate the client object.
            Dim client = New EasyUAClient()

            ' Obtain the serial number from the license info.
            Dim serialNumber As Long =
CUInt(client.LicenseInfo("Multipurpose.SerialNumber"))

            ' Display the serial number.
            Console.WriteLine("SerialNumber: {0}", serialNumber)

            ' Determine whether we are running as demo or trial.
            If (1111110000 <= serialNumber) And (serialNumber <= 1111119999) Then
                Console.WriteLine("This is a stock demo or trial license.")
            Else
                Console.WriteLine("This is not a stock demo or trial license.")
            End If
        End Sub
    End Class
End Namespace
```

Legal Concerns

Your usage of the software created with elements from OPC Data Client must comply with the terms of OPC Data Client EULA. In addition, because OPC Data Client contains and/or may depend on licensed material from 3rd parties, you must comply with license terms of such material as well. See **Licenses for Redistributed Material (Section 8.5.3)** for more details.

8.5.1 Managed Resource License Store

With the Managed Resource License Store, you embed your license into one of the assemblies that your application comprises of.

> This functionality is not available under (or the text does not apply to) COM development platform.

The main advantage of this method is that it does not require any additional actions during deployment. Also, because the Managed Resource License is the first one in the search order, you have a guarantee that if you properly place a specific valid license into the managed resource license store, it will be the one actually used - it cannot be changed by License Manager, for example. The disadvantage of this method is that you need to put extra code and data into your application, before building it.

Concepts

Follow the steps below in order to place a license into the Managed Resource License Store and use it. The procedure is written for C# in Visual Studio, but should be similar with other managed languages and tools.

1. Place the license file into your project. To do so, pick a folder in your project, and in **Solution Explorer**, right-click on it and select Add -> Existing Item. Then, select your license file; this is the file that has been given to you with OPC Data Client purchase. It has .BIN extension, and its name usually starts with a **"Key-Permanent-..."**. Press Add in order to finalize the selection.
2. Turn the license file in your project to an embedded resource: Select the file in **Solution Explorer**. Then, in the **Properties** window, select the Build Action row. Click on the drop-down button on its right side and select "Embedded Resource" from the list; alternatively, use up and down keys to make the same selection.
3. At the beginning of your code, before you call any OPC Data Client operations, obtain the static Instance Field from the LicensingManagement Class, and call the RegisterManagedResource Method with appropriate arguments. The first two arguments should always be **"QuickOPC"** and **"Multipurpose"**. The third argument determines the assembly where the license resides; you would typically use the Assembly.GetExecutingAssembly Method here, if the resource is in the same assembly as the code that is calling the RegisterManagedResource Method. The fourth argument is the namespace-qualified name of the managed resource. Visual Studio determines the namespace by concatenating the default namespace (as given in project properties) with names of the project folders (starting from the project root) the embedded resource resides in. So for example, if your default namespace is **MyApp**, and you have placed the embedded resource with license key (named **"Key-Permanent-ShareIt-1912345678-20180612.bin"**) to the **Resources** folder, the namespace-qualified name of the managed resource will be **"MyApp.Resource.Key-Permanent-ShareIt-1912345678-20180612.bin"**. If you are unsure, use the ILDASM tool.

Note that the actual presence and validity of the license is not checked at the time when the location is registered.

Example

The example below shows how to register a license located in an embedded managed resource.

C#

```
// Shows how to register a license located in an embedded managed resource.

using System;
using System.Reflection;
using OpcLabs.BaseLib.ComponentModel;
using OpcLabs.EasyOpc.UA;

namespace UADocExamples.Licensing
{
    class _LicensingManagement
    {
        public static void RegisterManagedResource()
        {
            // Register a license that is we embed as a managed resource in this
program.

            // The first two arguments should always be "QuickOPC" and "Multipurpose".
            // The third argument determines the assembly where the license resides.
            // The fourth argument is the namespace-qualified name of the managed
resource.
            LicensingManagement.Instance.RegisterManagedResource("QuickOPC",
```

```
"Multipurpose",
                Assembly.GetExecutingAssembly(),
                "UADocExamples.Licensing.Key-DemoOrTrial-WebForm-1999003494-
20180611.bin");

            // Instantiate the client object, obtain the serial number from the license
info, and display the serial number.
            var client = new EasyUAClient();
            long serialNumber = (uint)client.LicenseInfo["Multipurpose.SerialNumber"];
            Console.WriteLine("SerialNumber: {0}", serialNumber);

            // The license we ship for this purpose is a trial license with low runtime
limit, so it won't be of much use.
            // But you get the point...
        }
    }
}
```

VB.NET

```
' Shows how to register a license located in an embedded managed resource.

Imports System.Reflection
Imports OpcLabs.BaseLib.ComponentModel
Imports OpcLabs.EasyOpc.UA

Namespace UADocExamples.Licensing
    Friend Class _LicensingManagement
        Public Shared Sub RegisterManagedResource()

            ' Register a license that is we embed as a managed resource in this
program.

            ' The first two arguments should always be "QuickOPC" and "Multipurpose".
            ' The third argument determines the assembly where the license resides.
            ' The fourth argument is the namespace-qualified name of the managed
resource.
            LicensingManagement.Instance.RegisterManagedResource("QuickOPC",
"Multipurpose",
                    Assembly.GetExecutingAssembly(),
                    "UADocExamples.Licensing.Key-DemoOrTrial-WebForm-1999003494-
20180611.bin")

            ' Instantiate the client object, obtain the serial number from the license
info, and display the serial number.
            Dim client = New EasyUAClient()
            Dim serialNumber As Long =
CUInt(client.LicenseInfo("Multipurpose.SerialNumber"))
            Console.WriteLine("SerialNumber: {0}", serialNumber)

            ' The license we ship for this purpose is a trial license with low runtime
limit, so it won't be of much use.
            ' But you get the point...

        End Sub
    End Class
End Namespace
```

Troubleshooting

If the registration is not done properly, the component will continue the search for the license key in the order described in **Licensing Elements (Section 8.5)**. Usually, you will end up with a trial license instead, which is manifested by receiving a serial number other than the serial number of the license key you attempted to register. The serial number of stock demo or trial license is between 1111110000 and 1111119999 - see **Examples - Licensing - Obtain serial number (Section 13.2.1.1)**.

Here are the common reasons that can cause this issue:

- Your license key file is included in the project, but its Build Action (in **Properties**) is not set to "Embedded Resource". This happens easily, because (in Visual Studio) the file looks the same in **Solution Explorer**; the difference is just a subtle setting visible after you click on the file node in the **Solution Explorer** and inspect its **Properties**.
- The actual namespace of the managed resource does not match the one used with the RegisterManagedResource Method. This happens easily, because the actual namespace is determined using the default project namespace and a path of project folders in the solution, which is not always apparent, and there is no direct way (in Visual Studio) to check the resulting namespace.

If you cannot rule out the the cause is in incorrect resource namespace (or resource name, in general), we recommend to use the ILDASM tool (IL Disassembler, https://docs.microsoft.com/en-us/dotnet/framework/tools/ildasm-exe-il-disassembler) to figure out the precise actual name of your license key managed resource. You can use following steps:

1. **Start Developer Command Prompt** for Visual Studio.
2. Change current directory to the directory where the resulting assembly of your program resides (using the ***CD*** command).
3. Type ***ILDASM PEfilename*** , where *PEFilename* is the name of your assembly file (including file extension, typically .DLL or .EXE).
4. In the **IL DASM** window, double-click on the MANIFEST node.
5. In the **MANIFEST** window, find the license key managed resource and verify its namespace and name with the string used in the call to the RegisterManagedResource Method. Sometimes the differences are slight and not apparent at the first site; if you do not find a difference, we recommend that you copy the relevant part of the text from the MANIFEST window into your .NET source code.

For illustration, the part of the MANIFEST with the license key for our example looks like this:

```
.mresource public 'UADocExamples.Licensing.Key-DemoOrTrial-WebForm-1999003494-
20180611.bin'
{
  // Offset: 0x00000000 Length: 0x00000A68
}
```

8.5.2 Registry License Store

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

In This Topic

Manual License Deployment

When you use the Registry License Store, proper license (for runtime usage) must be installed on the target computer (the computer where the product will be running).

The standard method for installing the OPC Data Client license on runtime machines is manual: The user runs the License Manager utility (GUI or console-based), and installs the license by pointing the program to the license file stored on the disk.

If you have multiple OPC Data Client versions installed on the computer, you need to deploy the license that covers them all.

The subsequent part of the documentation describes how to automate the above procedure so that the user does not have to interact with the License Manager utility.

Registry Key

The license is stored in the registry, under the following key:

HKEY_LOCAL_MACHINE\SOFTWARE\Licensing\QuickOPC\Multipurpose

In order to install the license, this key and anything that is beneath it, must be properly deployed to the target machine.

Note: On 64-bit systems, the license is stored in 32-bit registry. When the registry is accessed from 64-bit application, you must use the following key instead:

HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Licensing\QuickOPC\Multipurpose

⚠ On 64-bit systems, if OPC Data Client is used from both 32-bit and 64-bit processes, you have to install the license into both 32-bit and 64-bit parts of the registry.

Access to the License

The license is stored in the registry. For the license to be recognized, the process (that runs OPC Data Client) must have read access to the corresponding registry keys. That is normally not a problem under "interactive" user accounts and traditional desktop applications, but it can be an issue when OPC Data Client runs as Windows service, or in hosted environments (such as IIS).

Specifically, IIS has one process for each Application Pool, and the application pool runs under a configurable user account. You need to assure that this user account has read access to the registry keys where the license is stored.

8.5.2.1 Deployment Automation

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

In order to automate the installation of the license, you first need to obtain the proper registry content that corresponds

to it.

Use the License Manager utility on the development computer, and install the license you intend to distribute. Then, start the REGEDIT utility, navigate to the registry key for the license, select it, and perform File -> Export command. You will obtain a registration file (with .REG extension) that contains the license information.

Your installation program can then use this information in various ways. For example, it can invoke the REGEDIT utility, and pass it the name of the generated .REG file on the command line. Alternatively, you can use other methods that your installation program provides for manipulating the registry, and simply have it replicate the information contained in the .REG file to the target system.

The license must not be modified in any way. Changing any of its fields (such as the Subject name) will render the license invalid.

Note: Take care on 64-bit systems, as both 32-bit and 64-bit REGEDIT applications exist, and each has a different view of the registry.

Some customers have notified us that when using Visual Studio to create an .MSI Installer, exporting the license from the registry and importing it into the Visual Studio project has modified the license fields and caused the license to be not recognized by the component. When in doubt, compare the registry content created by the License Manager against the one created by your installer. They must be precisely equal.

When a license in the registry is damaged, the License Manager may still display it as valid; but the component will not recognize it in runtime.

8.5.3 Licenses for Redistributed Material

Included Material

In This Topic

Your usage of the software created with elements from OPC Data Client must (in addition to the terms of OPC Data Client EULA) also comply with license terms of the 3rd-party material that comes with OPC Data Client. For the precise license terms, see **Licenses for 3rd-party Material (Section 2.6.1)**.

Depending on the particular subset of OPC Data Client elements that you redistribute or deploy with your application, the specific 3rd-party licensed material may not be included in your distribution/deployment. You only need to be concerned about the material that actually gets redistributed with your software. The table below explains which 3rd-party licensed material is needed when.

Material	Needed When
16x16 Free Application Icons	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
Diagone Icons	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
Discovery Icon Theme	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
Fugue 16px Additional Icons	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
Fugue 16px Additional Icons 2	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.

Fugue 16px Icons	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
Iconza Black Icons	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
Krypton software	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
SharpPcap	If your distribution contains the files of the **OpcLabs.Pcap** assembly.
PacketDotNet	If your distribution contains the files of the **OpcLabs.Pcap** assembly.
Ravenna 3D Icons	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.
Web Mini Icons	If your distribution contains the files of the **OpcLabs.BaseLibForms** assembly.

Typically, you just need to make an attribution to these somewhere in the product and/or its documentation. It always remains your responsibility, however, to comply with the precise license conditions of OPC Data Client EULA and the 3rd-party material that you redistribute.

Libraries under LGPL (such as SharpPcap, PacketDotNet) have additional requirements, such as the inclusion of the license text files.

Dependent Material

When you target .NET Standard development platform (see **Development Platforms (Section 2.3)**), OPC Data Client depends on (but does not ship with or include) various 3rd-party NuGet packages (mainly from Microsoft, and OPC Foundation), as described in the **Licensing (Section 2.6)** article. The application thay you build under .NET Standard with OPC Data Client therefore needs to contain the dependency packages (and their dependencies, recursively) as well, and you must make sure such usage complies with the licensing terms of the dependency packages.

9 Advanced Topics

9.1 Supported OPC Specifications

OPC Data Client directly supports following OPC specifications

(not in .NET Standard):

- all OPC DA (Data Access) 1.0x Specifications (Released)
- all OPC DA (Data Access) 2.0x Specifications (Released)
- all OPC DA (Data Access) 3.0x Specifications (Released)
- OPC Alarms and Events Custom Interface Standard 1.00, 1.01 and 1.10 (Released)
- all OPC Common 1.0x Specifications (Released)
- OPC Common 1.10 Specification (Draft)

OPC Data Client directly supports following OPC specifications (also in .NET Standard):

- OPC XML-DA 1.01 Specification (Released)
- OPC Unified Architecture 1.00 Specifications (Released)
- OPC Unified Architecture 1.01 Specifications (Released)
- OPC Unified Architecture 1.02 Specifications (Released)
- OPC Unified Architecture 1.03 Specifications (Released)
- OPC Unified Architecture 1.04 Specifications (Released) **(not in .NET Framework, COM or Excel, i.e. only in .NET Standard)**

Parts needed to support Data Access, Alarms & Conditions, Discovery and PubSub functionality are covered.

OPC Data Client is officially certified (by the means of its Connectivity Explorer application - because toolkits cannot be certified as such) by OPC Foundation (Certification Date: 09/24/2017, Certificate Number 1710CE0091), https://opcfoundation.org/products/view/52 . This is a renewed certification; OPC Data Client has been the first product of its kind (.NET-based client toolkit) that has ever been awarded this certification.

In This Topic

Specifically, the certified profiles are:

- Core Client Facet
- Base Client Behavior Facet
- Discovery Client Facet
- Attribute Read Client Facet
- Attribute Write Client Facet
- DataChange Subscriber Client Facet
- DataAccess Client Facet

OPC Data Client supports more facets than just those that have been certified. See **Supported OPC UA Profiles (Section 9.1.1)** for the full list.

You may also want to consult the list of **Supported OPC UA Services (Client-Server) (Section 9.1.2)** and **Supported OPC UA Security Policies (Section 9.1.3)** supported by OPC Data Client.

OPC Foundation Certified for Compliance logo is a trademark of the OPC Foundation and may be used only by written permission of the OPC Foundation. Any unauthorized use of the Certified for Compliance logo is prohibited.

President

The reproduction of this official certificate is strictly prohibited without prior written consent from the OPC Foundation Certification Test Lab.

The certification has been performed using the Connectivity Explorer application, built with OPC Data Client and targeting the .NET Framework development platform.

9.1.1 Supported OPC UA Profiles

OPC Data Client supports following facets of OPC UA Profiles. Categories and profiles are sorted alphabetically.

In This Topic

Here, we can only list profiles that are actually defined by the OPC Foundation. OPC Data Client also supports features for which there are no standard profiles defined. Specifically, in the Security and Transport categories, OPC Data Client has support for additional security policies and transports other than just those listed here.

For this reason, the OPC UA Profiles list should not be understood as a list of OPC Data Client features with regard to OPC UA - it is only their subset. The purpose of this list is to allow matching of the client capabilities against a list of requirements, if the requirements are expressed in terms of OPC UA Profiles.

Client Category

Alarm & Condition

- A & C Alarm Client Facet
- A & C Address Space Instance Client Facet
- A & C Base Condition Client Facet
- A & C Base Refresh2 Client Facet
- A & C Dialog Client Facet
- A & C Enable Client Facet

Core Characteristics

- Address Space Lookup Client Facet
- Base Client Behaviour Facet
- Core 2017 Client Facet
- Core Client Facet [deprecated]
- Discovery Client Facet
- Documentation - Client
- Global Discovery Client Facet
- Multi-Server Client Connection Facet
- Subnet Discovery Client Facet

Data Access

- Attribute Read Client Facet
- Attribute Write Client Facet
- DataAccess Client Facet
- DataChange Subscriber Client Facet

Event Access

- Base Event Processing Client Facet
- Event Subscriber Client Facet
- Notifier and Source Hierarchy Client Facet

- HTTPS UA-XML **(not in .NET Standard)**
- UA-TCP UA-SC UA-Binary

PubSub

- PubSub UDP UADP *(note: IPv4 and IPv6)*
- PubSub MQTT UADP
- PubSub MQTT JSON

9.1.2 Supported OPC UA Services (Client-Server)

Sometimes, a list of supported services is used to compare SDKs, libraries or toolkits. For this reason, we provide the list of OPC UA services OPC Data Client supports, here. It should be noted, however, that comparison of supported services should not be done blindly. Always take following concerns into consideration:

- The number of services is intentionally kept low in OPC UA. The distinguishing factors lie deeper - in the various arguments that these services accept. Many services provide very rich functionality depending on the arguments they are passed, and the fact that a particular service is supported does not tell much by itself, without further qualification. You need to compare the actual capabilities of the toolkits, as seen from the user's perspective, instead.
- Many toolkits provide very thin layer over the OPC UA service calls, and that's all they do. They then leave it onto you to assemble the arguments, then call the services in the proper way and sequence, and interpret the results. That's easy for the toolkit author, but does not give you any added value. And, it's easy, but kind of useless, to expose many OPC UA services in this way, if all the toolkit does is to make it possible to invoke them. OPC Data Client has a very different approach. The individual OPC UA service are not exposed to you directly. Instead, you are given high level, task-oriented methods, that in turn call the necessary OPC UA services internally - sometimes, many of them for one OPC Data Client method.

In This Topic

The OPC UA services that OPC Data Client supports are listed below.

Discovery Service Set

- FindServers
- FindServersOnNetwork
- GetEndpoints

SecureChannel Service Set

- OpenSecureChannel
- CloseSecureChannel

Session Service Set

- CreateSession
- ActivateSession
- CloseSession

NodeManagement Service Set

(none)

View Service Set

- Browse
- BrowseNext
- TranslateBrowsePathsToNodeIds

Query Service Set

(none)

Attribute Service Set

- Read
- Write

Method Service Set

- Call

MonitoredItem Service Set

- CreateMonitoredItems
- ModifyMonitoredItems
- DeleteMonitoredItems

Subscription Service Set

- CreateSubscription
- Publish
- Republish
- DeleteSubscriptions

9.1.3 Supported OPC UA Security Policies

Client-Server

OPC Data Client supports following OPC UA security policies for Client-Server:

Name	Security Policy URI
Aes128_Sha256_RsaOaep **(not in .NET Framework, COM or Excel, i.e. only in .NET Standard)**	http://opcfoundation.org/UA/SecurityPolicy#Aes128_Sha256_RsaOaep
Aes256_Sha256_RsaPss **(not in .NET Framework, COM or Excel, i.e. only in .NET Standard)**	http://opcfoundation.org/UA/SecurityPolicy#Aes256_Sha256_RsaPss
Basic128Rsa15 **(obsolete)**	http://opcfoundation.org/UA/SecurityPolicy#Basic128Rsa15
Basic256	http://opcfoundation.org/UA/SecurityPolicy#Basic256
Basic256Sha256	http://opcfoundation.org/UA/SecurityPolicy#Basic256Sha256
None	http://opcfoundation.org/UA/SecurityPolicy#None

9.2 OPC Interoperability

The OPC Data Client components have been extensively tested for OPC interoperability, with various OPC servers from many vendors, and on different computing environments. The tests also include regular participation in OPC Foundation's Interoperability Workshops, where OPC software is intensively "grilled" for interoperability.

Having tried so many different OPC servers to connect to, we have encountered different (though still correct) interpretations of the same OPC specifications, and also certain common (and less common) divergences from the specifications. OPC Data Client components do not try to "turn down" any OPC server for compliance problems. Just the opposite: Wherever possible, we have taken a "relaxed" approach to how the OPC servers are written, and allow and accept the above mentioned variations. This gives OPC Data Client even wider interoperability scope.

Based on the interoperability results (which can be viewed on OPC Foundation's web site), OPC Data Client.NET and OPC Data Client-COM have also been granted the OPC Foundations' "Self-tested for Compliance" logo. Note that in contrast with the logo title, the conditions of this logo program actually require the OPC client software be tested in presence and with cooperation of OPC Foundation's Test Lab delegate.

9.2.1 OPC-UA via UA Proxy

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

The Unified Architecture (UA) is the next generation OPC standard that provides a cohesive, secure and reliable cross platform framework for access to real time and historical data and events.

The OPC Data Client-UA product allows native connections to OPC Unified Architecture servers.

OPC Data Client-Classic is not a native OPC UA client, but you can still use it to connect to OPC UA servers, using so-called UA COM Proxy (available e.g. from OC Foundation as part of OPC UA COM Interop Components).

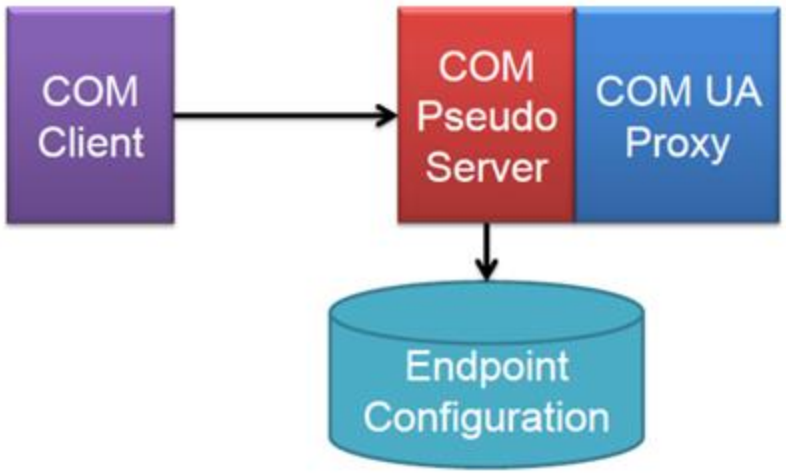
The OPC UA COM Interop Components from OPC Foundation make it possible for existing COM-based applications to

communicate with UA applications. OPC Labs is using them to add UA support to existing products. Support for OPC UA COM Interop Components is not currently provided.

The components that allows COM clients (such as OPC Data Client-COM and OPC Data Client.NET) to talk to UA server is called the UA Proxy (or UA COM Proxy). It is a DCOM server that implements the different OPC COM specifications. A COM client (OPC Data Client) uses DCOM to talk to this proxy, usually on the local machine (i.e. the same machine where the client is), and the proxy translates OPC COM calls into UA calls, and fetches the information as required from the UA server. It is a dynamic operation – all the information about address space and data values is retrieved dynamically from the UA server.

The UA COM Proxy is a DCOM server, meaning that it has its own ProgID and CLSID (class ID). However, there needs to be some mapping between the particular ProgID and a particular UA endpoint. The UA COM proxy relies on a concept of a Pseudo-server, which maps a ProgID to a specific UA endpoint, which is stored in the configuration file. The configuration tool that is made available as part of OPC UA COM Interop Components has the ability to select a UA endpoint and create one of these pseudo-servers that a COM client can then connect to. This endpoint configuration file is stored on disk in XML format.

This file also stores state information, which is necessary for replicating COM client configuration across multiple machines. If you set up a client on a particular machine, talking to a particular UA server, and do all the necessary configuration, and you then want to take the configuration and install it on multiple other machines, you can simply copy that endpoint configuration file along. The file contains the ProgID and CLSID of the pseudo-server, and the endpoint information.



The configuration tool for OPC UA COM Proxy can be found in your Start menu, under OPC Foundation → UA SDK 1.01 → UA Configuration Tool. In order to make a UA server visible to COM clients through the UA COM Proxy, select the "Manage COM Interop" tab, press the "Wrap UA Server" button, and fill in the information required by the program. You need to specify the endpoint information for a UA server (possibly using a UA discovery mechanism), the UA connection

parameters, and finally the COM pseudo-server CLSID and ProgID (the tool offers reasonable defaults). After you have finished this step, the pseudo-server appears in the list, and OPC COM clients (OPC Data Client-COM, OPC Data Client.NET) can connect to it.

9.2.2 OPC "Classic" via UA Wrapper

OPC “Classic” refers to a set of older OPC specifications that use Microsoft DCOM as their underlying communication mechanism. These are specifications such as OPC Data Access, OPC Alarms and Events, and others.

OPC Data Client-Classic products (OPC Data Client.NET and OPC Data Client-COM) allow native connections to OPC “Classic” servers.

OPC Data Client-UA is not a native OPC “Classic” client, but you can still use it to connect to OPC “Classic” servers, using so-called UA Wrapper (for OPC COM Servers) that is available from e.g. from the OPC Foundation (as part of OPC UA COM Interop Components). The OPC UA COM Interop Components from OPC Foundation make it possible for existing COM-based applications to communicate with UA applications.

9.3 Instrumentation

9.3.1 Application Configuration

OPC Unified Architecture is a rich specification that allows the participating software use different approaches and parameters to achieve their goals. As a result, there is large number of variable settings that can be tweaked to influence the performance, or achieve full interoperability.

OPC Data Client-UA attempts to determine many of these setting automatically, and also exposes the most important ones to the developer by means of properties on the various OPC Data Client-UA objects. As long as this approach works well for your application, you do not have to do anything extra to configure the UA application.

One important piece of information is the subject name of the application instance certificate. The component uses the subject name to locate the instance certificate in the certificate store, and if it is not found, it attempts to create a new instance certificate, and store it with the subject name. The default subject name is created automatically, based on the description (title) of the application assembly, or (if the preceding yields a name that is too generic, such as ‘mscorlib’ in many hosted scenarios) from other sources of information, such as the executable’s FileVersionInfo, or a main module name.

If you want to use a specific subject name for your application instance certificate, set the EasyUAClient.SharedParameters.EngineParameters.ApplicationParameters.ApplicationCertificateSubject property accordingly.

Other parameters that influence the application certificate creation are EasyUAClient.SharedParameters.EngineParameters.ApplicationParameters.ApplicationName, ApplicationUriString, and ProductUriString.

If, for any reason, you need to change parameters that cannot be influenced using various properties on OPC Data Client-UA objects, you can decide to provide the whole set of parameters yourself. To do so, make sure that the EasyUAClient.SharedParameters.EngineParameters.ConfigurationSources property contains the UAConfigurationSources.AppConfig bit set (in the default value setting, this bit is set, together with UAConfigurationSources.Internal).

With this setting on, the whole set of parameters for OPC UA .NET Stack and SDK becomes accessible to you. The UA configuration file can be placed alongside the application’s executanle, and given the same, but a file extension of

"**.config.xml**". Such file will automatically be found and used, with no extra settings needed. If you want to place the UA configuration file elsewhere or give it a different name, you need to make several other steps yourself then:

1. Add an entry for a new configuration section, named "UAClientEngine", into the application configuration file. In Visual Studio, you typically design the contents of the application configuration file is in the **app.config** file in your project. If you do not have this file in your project, add it first. After making this change, the beginning of this file may look like this:

   UAClientEngine section declaration in application configuration file

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <configuration>
     <configSections>
       <section name="UAClientEngine"
   type="Opc.Ua.ApplicationConfigurationSection,Opc.Ua.Core" />
     </configSections>

   ...
   ```

2. Add a "UAClientEngine" element into the application configuration file. The main purpose of this element is to refer to an external XML file that contains the UA configuration. The element may look like this:

   UAClientEngine section definition in application configuration file

   ```
   <UAClientEngine>
     <ConfigurationLocation
   xmlns="http://opcfoundation.org/UA/SDK/Configuration.xsd">
       <FilePath>MyApplication.Config.xml</FilePath>
     </ConfigurationLocation>
   </UAClientEngine>
   ```

3. Create the UA configuration file with the name specified above, and fill it with settings you need. Unless specified otherwise, the file should be placed alongside the executable of your application.

Please refer to the OPC UA .NET Stack and SDK documentation for information on sections and parameters in the **app.config** file and in the UA configuration file. Following are examples of what can be changed using the UA configuration file:

- Transport configurations
- Transport quotas and timeouts
- Trace configuration

If you switch your application so that its UA configuration is placed in an external file like described above, you can then also use the "UA Configuration Tool" from OPC Foundation to configure certain parameters for the application (mainly, the security-related settings).

When the UAConfigurationSources.Internal bit is set as well, a failure to load the UA configuration from file causes OPC Data Client-UA to determine and provide all configuration parameters automatically, which is therefore the default behavior if no UA configuration file is present.

9.3.2 Event Logging

9.3.2.1 Event Logging for OPC "Classic"

Currently, OPC Data Client for OPC “Classic” specifications does not have support for event logging.

9.3.2.2 Event Logging for OPC UA

The OPC Data Client-UA does not log events on itself, but allows you to implement such functionality. It generates notifications with log entries that contain the necessary data. You can receive these notifications, and implement any kind of event logging with them in your code.

The EasyUAClient component has a static LogEntry event. This event is raised for loggable entries originating in the OPC-UA client engine and the EasyUAClient component. Each event notification carries a LogEntryEventArgs object, which contains information such as the source of the event, the event message, event type, timestamp, etc.

Note that you should not programmatically use the logging event notifications for any kind of direct actions on the OPC subsystem. For example, the notifications that inform you about the connections and disconnections to/from OPC servers have no direct relation to your OPC method calls, because the component internally merges the requests from multiple objects, and also makes optimizations to prevent unnecessary disconnections etc. The purpose of event logging is different from OPC communication.

In COM, you cannot access static members of the EasyUAClient object, and therefore you cannot directly use its LogEntry event. To get around this, create an instance of the EasyUAClientConfiguration object instead, and use its (non-static) LogEntry event to achieve the same result.

C#

```
// This example demonstrates the loggable entries originating in the OPC-UA client
engine and the EasyUAClient component.

using System;
using OpcLabs.BaseLib.Instrumentation;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UADocExamples._EasyUAClient
{
    class LogEntry
    {
        public static void Main1()
        {
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET
Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"
```

```
            // Hook static events
            EasyUAClient.LogEntry += EasyUAClientOnLogEntry;

            try
            {
                // Do something - invoke an OPC read, to trigger some loggable entries.
                var client = new EasyUAClient();
                try
                {
                    client.ReadValue(endpointDescriptor,
"nsu=http://test.org/UA/Data/;i=10853");
                }
                catch (UAException uaException)
                {
                    Console.WriteLine("*** Failure: {0}",
uaException.GetBaseException().Message);
                    return;
                }

                Console.WriteLine("Processing log entry events for 1 minute...");
                System.Threading.Thread.Sleep(60 * 1000);

                Console.WriteLine("Done.");
            }
            finally
            {
                // Unhook static events
                EasyUAClient.LogEntry -= EasyUAClientOnLogEntry;
            }
        }

        // Event handler for the LogEntry event. It simply prints out the event.

9.4 Debugging

In OPC-UA, the component attempts to detect whether a debugger is attached to the application, and if so, it uses a different, much slower keep-alive interval (this keep-alive interval is controlled by the UAClientSessionParameters.KeepAliveIntervalDebug property, and defaults to 1 day). This allows the developer to break into the debugger and examine the status of the program, without causing the OPC-UA sessions be disconnected due to the fact that keep-alives are not being exchanged while the execution is suspended.

9.5 Object Serialization

OPC Data Client.NET and OPC Data Client-UA allows you to easily store objects (and object graphs, i.e. interconnected objects) into files and streams, and also to load them back.

Two types of serialization are supported:

- Basic serialization using Serializable attribute and/or ISerializable interface. This serialization type is typically used with BinaryFormatter for storing objects in a binary format.
- XML serialization using XmlSerializer and IXmlSerializable. This serialization provides objects storage in XML format.

Practically all OPC Data Client objects (and their collections and dictionaries) can be serialized and deserialized. For example:

- You can load and store EasyDAClient**,** EasyAEClient and EasyUAClient objects (their instance properties, i.e. various parameters, are serialized).
- You can load and store parameter objects, such as DAGroupParameters.
- You can load and store arguments (and arrays of arguments) passed to functions, such as lists of items to be subscribed to (DAItemGroupArguments). This functionality can be used e.g. with storing lists of subscribed items in file, outside your application code.
- You can load and store results of browsing and querying (e.g. DANodeElementCollection, AECategoryElementCollection, and UANodeElementCollection).
- You can load and store results of reading (e.g. DAVtq, or UAAttributeData).
- You can load and store condition states (AEConditionState) and event data (AEEventData).
- You can load and store all notification data contained in event arguments, for OPC Data Access item changes (EasyDAItemChangedEventArgs), OPC Alarms and Events notifications (EasyAENotificationEventArgs), or OPC Unified Architecture monitored item changes (EasyUADataChangeNotificationEventArgs). This functionality can be used e.g. for easy logging of significant changes and events in the underlying system.

9.6 Internal Optimizations

OPC is quite “sensitive” to proper usage, with regard to efficiency. OPC Data Client performs many internal optimizations, and uses the knowledge of proper approaches and procedures to effectively handle the communication with OPC servers.

Here are some of the optimizations implemented in OPC Data Client.NET and OPC Data Client-COM:

- Wherever possible, OPC operations are performed on multiple elements at once.
- OPC items with similar update rates are put into a common OPC group.
- OPC items with similar percentage deadbands are put into a common OPC group.
- OPC items are not removed from OPC groups immediately, but only if not used for certain amount of time.
- OPC item data is held in memory, and if fresh enough, the value from memory is taken, and no OPC call is made to satisfy the Read request.
- OPC asynchronous calls are preferred over synchronous calls.
- Minimum update rates are enforced, so that the system cannot be easily overloaded.
- Multiple uses of the same OPC server or same OPC item in the user application are merged into a single request to the OPC.
- Internal queues are used to make sure that OPC callbacks cannot be blocked by user code.

Here are some of the optimizations implemented in OPC Data Client-UA:

- Wherever possible, OPC operations are performed on multiple elements at once.
- OPC UA sessions are not closed immediately, but only if not used for certain amount of time.
- Multiple uses of the same OPC server endpoint in the user application are merged into a single request.

In OPC Data Client-UA, you can call a static method EasyUAClient.CloseAll to close all unused sessions that are open to OPC-UA servers.

9.7 Failure Recovery

The OPC communication may fail in various ways, or the OPC client may get disconnected from the OPC server. Here are some examples of such situations:

- With OPC Classic, the OPC server may not be registered on the target machine – permanently, or even temporarily, when a new version is being installed.
- With OPC UA, the OPC server may not be running or registered with the discovery service on the target machine – permanently, or even temporarily, when a new version is being installed.
- The (DCOM, TCP, Web service or other) communication to the remote computer breaks due to unplugged network cable.
- The remote computer running the OPC server is shut down, or restarted, e.g. for security update.
- The configuration of the OPC server is changed, and the OPC information (item in OPC Classic, node and attribute in OPC UA) referred to by the OPC clients no longer exists. Later, the configuration could be changed again and the OPC item may reappear.
- The OPC server indicates a serious failure to the OPC client.
- The OPC Classic server asks its clients to disconnect, e.g. for internal reconfiguration.

OPC Data Client handles all these situations, and many others, gracefully. Your application receives an error indication, and the component internally enters a "wait" period, which may be different for different types of problems. The same operation is not reattempted during the wait period; this approach is necessary to prevent system overload under error conditions. After the wait period elapses, OPC Data Client will retry the operation, if still needed at that time.

All this logic happens completely behind the scenes, without need to write a single line of code in your application. OPC Data Client maintains information about the state it has created inside the OPC server, and re-creates this state when the OPC server is disconnected and then reconnected. In OPC Classic, objects like OPC groups and OPC items are restored to their original state after a failure. In OPC UA, objects like OPC subscriptions and OPC monitored items are restored to their original state after a failure.

Even if you are using the subscriptions to OPC items (in OPC Classic) or to monitored items (in OPC UA) or events, OPC Data Client creates illusion of their perseverance. The subscriptions outlive any failures; you do not have to (and indeed, you should not) unsubscribe and then subscribe again in case of error. After you receive event notification which indicates a problem, simply stay subscribed, and the values will start coming in again at some future point.

In OPC Data Client-UA, you can call a static method EasyUAClient.RetryAll to force a retrial on all objects that are in a failure state. This method terminates the waiting delay, and causes all such objects to be retried on next opportunity.

9.8 Timeout Handling

In OPC Data Client-UA, timeout values for certain OPC Data Client tasks are accessible via properties on the EasyUAClient object. The explanation of the individual timeout values is provided in the Reference documentation.

The remainder of this chapter applies mainly to OPC Data Client "Classic".

The core OPC Data Client methods (ReadItem, ReadItemValue, WriteItemValue, and their counterparts that work with multiple items at once) are all implemented as synchronous function calls with respect to the caller, i.e. they perform some operation and then return, passing the output to the caller at the moment of return. However, this does not mean that the component makes only synchronous calls to OPC servers while you are calling its methods. Instead, OPC Data Client works in background (in separate threads of execution) and only uses the method calls you make as "hints" to perform proper data collection and modifications.

Internally, OPC Data Client maintains connections to requested OPC servers and items, and it establishes the connections when you ask for reading or writing of certain OPC item. OPC Data Client eventually disconnects from these servers and items if they are no longer in use or if their count goes beyond certain limits, using its own LRU-based algorithm (Least Recently Used).

When you call any of the core OPC Data Client methods, the component first checks whether the requested item is already connected and available inside the component. If so, it uses it immediately (for reading, it may provide a cached value of it). At the same time, the request that you just made by calling the method is used for dynamic decisions on how often the item should be updated by the server etc.

If the item is not available, OPC Data Client starts a process to obtain it. This process has many steps, as dictated by the OPC specifications, and it may take some significant time. The method call you just made does not wait indefinitely until the item becomes available. Instead, it uses certain timeout values, and if the item does not become available within these timeouts, the method call returns. The connection process is totally independent of the method that was called, meaning that no problem in the connection process (even an ill-behaved server, or a broken DCOM connection) can cause the calling method to wait longer than the timeouts dictate.

The timeout values are accessible via InstanceParameters.Timeouts property on the EasyDAClient object. The explanation of the individual timeout values is provided in the Reference documentation.

Note that if the nature of the situation allows the component to determine that the item will NOT be available, the method will return earlier (before the timeouts elapse) with the proper error indication. This means that not every connection problem causes the method to actually use the full value of the timeouts. For example, when the server refuses the item because the item has an incorrect name, this error is passed immediately to the caller.

It is important to understand that even if the method call times out because the connection process was not finished in time, the connection process itself is not cancelled and may continue internally. This means that next time the same item is requested, it may be instantly available if the connection process has finished. In other words, the timeouts described above affect the way the method call is executed with respect to the caller, but do not necessarily affect at all the way the connection is performed.

When you create an EasyDAClient object, the timeout values are set to reasonable defaults that work well with reporting or computation type of OPC applications. In these applications, you know that you MUST obtain certain value within a timeout, otherwise the application will not be doing what is intended to do: e.g. the report will not contain valid data, or the computations will not be performed. When the requested item is not instantly available (for example, the server is not started yet), the application can afford delays in processing (method calls made to EasyDAClient object may block the execution for certain time). For this kind of applications, you may leave the default timeout values, or you may adjust them based on the actual configuration and performance of your system.

There is also a different kind of applications, typically an HMI screen, which wants to periodically update the values of controls displayed to the user. The screen usually contains larger number of these controls that are refreshed in a cyclic way by the application. If possible, you should use subscription-based updated for these applications, and in such case the timeouts are of much lesser importance. But, in some application the subscriptions are not practical, and you resort to periodic reading (polling). The fact that SOME data is not instantly available should not be holding the update of others. It is perfectly OK to display an indication that the data is not available momentarily, and possibly display them in some future refresh cycle when they become available. For this kind of application, you may prefer to set all the above mentioned timeout properties to lower values. This assures that the refresh loop always goes quickly over all the controls on the screen, no matter whether the data is available for them immediately, or only in a postponed fashion.

To simplify this explanation, you can also say that if you need the OPC values for further *sequential* processing, reasonably long timeouts are needed (and the defaults should serve well in most situations). If you are refreshing the data on a *cyclic* basis by polling, you will probably need to set the timeouts to lower values.

9.9 Data Types

OPC specifications have their own rules about data types, and these have to be reflected in the components and applications. This chapter describes the details of the data type handling.

9.9.1 Data Types in OPC Classic

OPC Data Access specification is based on COM, and uses Windows VARIANT type (from COM Automation) for representing data values.

Note: Some OPC servers even use certain VARIANT types that are not officially supported by Microsoft.

Microsoft .NET has a different concept, and all data is represented using an Object type. Conversions between the two are available, but not always fully possible.

In addition, not everything that can be stored in an Object can later be processed by all .NET tools and languages. Microsoft has created so-called Common Language Specification (CLS), which has certain rules and restrictions that, if followed, guarantee cross-language compatibility. Public OPC Data Client.NET components (assemblies) are fully CLS compliant, and that includes the way the data types are converted to and from OPC types.

OPC Data Client.NET converts data from COM to .NET according to following table:

COM type (VARIANT)	.NET type (Object)
VT_EMPTY	System.Object (null reference)
VT_NULL	System.DBNull (singleton class)
VT_I2	System.Int16
VT_I4	System.Int32
VT_R4	System.Single
VT_R8	System.Double
VT_CY	System.Decimal
VT_DATE	System.DateTime
VT_BSTR	System.String
VT_DISPATCH	System.Object (not tested)
VT_ERROR	System.Int32
VT_BOOL	System.Boolean
VT_VARIANT	converted type of the target VARIANT
VT_DECIMAL	System.Decimal
VT_I1	System.Int16

VT_UI1	System.Byte
VT_UI2	System.Int32
VT_UI4	System.Int64
VT_I8	System.Int64
VT_UI8	System.Decimal
VT_INT	System.Int32
VT_UINT	System.Int64
VT_ARRAY | *vtElement*	System.Array of the converted *vtElement* type

Types that are highlighted do not convert from COM to their "natural" .NET counterparts, because the corresponding .NET type is not CLS compliant. Instead, a "wider" type that is CLS compliant is chosen.

Types not listed in the above table at all are not supported.

Strings are internally represented in Unicode wherever possible.

OPC Data Client-COM is meant to be used from applications based on COM Automation, and in general, any valid VARIANT can be processed by such application. Some automation tools and programming languages, however, have restrictions on types of data they can process. If your tool does not support the data type that the OPC server is using, without OPC Data Client, you would be out of luck.

In order to provide the ability to work with widest range of OPC servers and the data types they use, OPC Data Client-COM converts some data types available in OPC. We have made a research into the data types supported by various tools, and OPC Data Client-COM uses a subset of VarType types that is guaranteed to work in most tools that are in use today (one of the most restrictive languages appears to be VBScript).

Note that the OPC Data Client-COM only converts the data that it passes to your application – either in output arguments of property accessors or methods, or input arguments in event notifications. In the opposite direction, i.e. for data that your application passes to OPC Data Client-COM, we use very "relaxed" approach, and accept the widest range of possible data types.

OPC Data Client-COM converts data from OPC Data Access according to following table:

VARTYPE in OPC Data Access	**VARTYPE In OPC Data Client-COM**
VT_EMPTY	VT_EMPTY
VT_NULL	VT_NULL
VT_I2	VT_I2
VT_I4	VT_I4
VT_R4	VT_R4
VT_R8	VT_R8
VT_CY	VT_CY
VT_DATE	VT_DATE
VT_BSTR	VT_BSTR

VT_DISPATCH	VT_DISPATCH
VT_ERROR	VT_R8
VT_BOOL	VT_BOOL
VT_VARIANT	VT_VARIANT
VT_DECIMAL	VT_DECIMAL
VT_I1	VT_I2
VT_UI1	VT_UI1
VT_UI2	VT_I4
VT_UI4	VT_R8
VT_I8	VT_R8 (may lose precision)
VT_UI8	VT_R8 (may lose precision)
VT_INT	VT_I4
VT_UINT	VT_R8
VT_ARRAY | *vtElement*	VT_ARRAY | VT_VARIANT(*vtElement*) *(see note below)

Types that are highlighted are converted to a different data type. If a precise match does not exist, a "wider" type is chosen.

Types not listed in the above table at all are not supported.

Strings are internally represented in Unicode wherever possible.

9.9.2 Data Types in OPC-UA

OPC Unified Architecture has its own type system, based on a set of built-in types, and a type graph that supports inheritance and creation of structured types.

The types in Microsoft .NET are different, and all data is represented using an Object type and its derivatives. Conversions between the two are available, but not always fully possible.

In addition, not everything that can be stored in an Object can later be processed by all .NET tools and languages. Microsoft has created so-called Common Language Specification (CLS), which has certain rules and restrictions that, if followed, guarantee cross-language compatibility. Public OPC Data Client components (assemblies) are fully CLS compliant, and that includes the way the data types are converted to and from OPC types.

OPC Data Client-UA converts data from OPC-UA to .NET according to following table:

OPC-UA type	**.NET type (Object)**
Boolean	System.Boolean
Byte	System.Byte
ByteString	System.Byte[]
DataValue	OpcLabs.EasyOpc.UA.UAAttributeData

DateTime	System.DateTime (UTC)
Double	System.Double
ExpandedNodeId	OpcLabs.EasyOpc.UA.AddressSpace.UANodeId
ExtensionObject	when the OPC UA Complex Data extension is enabled (the default): UAGenericObject Class when the OPC UA Complex Data extension is disabled: OpcLabs.EasyOpc.UA.UAExtensionObject
Float	System.Single
Guid	System.Guid
Int16	System.Int16
Int32	System.Int32
Int64	System.Int64
LocalizedText	System.String (see note)
NodeId	OpcLabs.EasyOpc.UA.AddressSpace.UANodeId
QualifiedName	OpcLabs.EasyOpc.UA.AddressSpace.UAQualifiedName
SByte	System.Int16
StatusCode	OpcLabs.EasyOpc.UA.UAStatusCode
String	System.String
UInt16	System.Int32
UInt32	System.Int64
UInt64	System.Decimal
XmlElement	System.Xml.XmlElement
array of *elementType*	System.Array of the converted *elementType*

Note: LocalizedText is converted to its text part.

Types that are highlighted do not convert from OPC-UA to their "natural" .NET counterparts, because the corresponding .NET type is not CLS compliant. Instead, a "wider" type that is CLS compliant is chosen.

Types not listed in the above table at all are not supported.

Strings are internally represented in Unicode.

In OPC Data Client-UA for COM, the same types as in OPC Data Client-UA for .NET are used. The type conversions between COM and .NET and performed by the Microsoft interoperability layer. Reference to Microsoft documentation for correspondences between the .NET and COM types.

9.10 Multithreading and Synchronization

The EasyDAClient, EasyAEClient and EasyUAClient objects and all their related helper objects are thread-safe.

In OPC Data Client.NET and OPC Data Client-UA, if you are hooking to the event notifications provided by the EasyDAClient , EasyAEClient or EasyUAClient component, or processing these notifications in your callback methods, make sure that you understand how the component generates these events and what threading issues it may involve. This is how it works:

The EasyDAClient, EasyAEClient or EasyUAClient object has a SynchronizationContext property. This property can either be set to a null reference, or to an instance of System.Threading.SynchronizationContext class. When the SynchronizationContext is set to a null reference, EasyDAClient, EasyAEClient or EasyUAClient calls any event handlers or callback methods on its own internal thread, which is possibly different from any threads that you have in your application. When the SynchronizationContext is set to a concrete instance, the synchronization model implemented by this object is used. The EasyDAClient, EasyAEClient or EasyUAClient then typically uses the Post method of this synchronization context to invoke event handlers in your application.

When the EasyDAClient, EasyAEClient or EasyUAClient object is initially created, it attempts to obtain the synchronization context from the current thread (the thread that is executing the constructor). As a result, if the thread constructing the EasyDAClient, EasyAEClient or EasyUAClient object has a synchronization context associated with it, it will become the value of the SynchronizationContext property. Otherwise, the SynchronizationContext property will be set to a null reference. This way, the synchronization context propagates from the constructing thread.

Access to Windows Forms controls or WPF controls is not inherently thread safe. If you have two or more threads manipulating the state of a control, it is possible to force the control into an inconsistent state. Other thread-related bugs are also possible, such as race conditions and deadlocks. It is important to make sure that access to your controls is performed in a thread-safe way. Thanks to the mechanism described above, this is done automatically for you, provided that the constructor of the EasyDAClient, EasyAEClient or EasyUAClient object is called on the form's main thread, as is the case if you place the EasyDAClient , EasyAEClient or EasyUAClient component on the form's design surface in Visual Studio. This works because by default, Windows Forms set the synchronization context of the form's main thread to a properly initialized instance of System.Windows.Forms.WindowsFormsSynchronizationContext object.

Similarly, Windows Presentation Foundation (WPF) applications use System.Windows.Threading.DispatcherSynchronizationContext to achieve the same thing.

If your application is not based on the above frameworks, or is using them in an unusual way, you may have to take care of the synchronization issues related to event notification yourself, either by directly coding the synchronization mechanism, or by implementing and using a class derived from System.Threading.SynchronizationContext.

In OPC Data Client.NET and OPC Data Client-UA, objects in the Forms namespaces follow the general Windows Forms rules and conventions, meaning that any public static (Shared in Visual Basic) type members are thread-safe. Any instance members are not guaranteed to be thread safe.

In OPC Data Client-COM and OPC Data Client-UA for COM, if you are hooking to the event notifications provided by the EasyDAClient, EasyAEClient or EasyUAClient component, make sure that you understand how the component generates these events and what threading issues it may involve. The event notifications generated by EasyDAClient, EasyAEClient or EasyUAClient object originate from a thread that may be (and generally is) different from the thread that you used to create an instance of the object or call its methods. The code in your event handler must be prepared to deal with it.

A typical issue that arises is that access to Windows controls is not inherently thread-safe, and should be done from a dedicated thread only. It is important to make sure that access to your controls is performed in a thread-safe way. This typically involves setting up some communication mechanism between the event handler code, and a thread dedicated to handling the user interface of your application.

9.11 64-bit Platforms

You can create 32-bit or 64-bit, or platform-independent applications with OPC Data Client. 32-bit applications can also

run on 64-bit systems. 64-bit applications can only run on 64-bit systems. Normally, you will target your application to "Any CPU", and the same code will then run on both x86 and x64 platforms.

Supported platforms are x86 (i.e. 32-bit), and x64 (i.e. 64-bit). The product has not been tested and is not supported on the Itanium platform (IA-64).

When you use OPC Data Client for COM development, the components are compiled using the "just-in-time" by the .NET runtime for either 32-bit or 64-bit execution, depending on the bitness of the process that loads the OPC Data Client components.

9.11.1 32-bit and 64-bit Code

OPC Data Client.NET (for OPC Classic; not OPC Data Client-UA) assemblies contain certain parts in native 32-bit code (for x86 platform) and in native 64-bit code (for x64 platform). OPC Data Client.NET uses a special technique to load the so-called mixed mode assemblies (assemblies that contain both managed and native code) for a proper processor architecture.

OPC XML-DA support in OPC Data Client is written fully in managed code, and is not using the mixed mode assemblies.

Any application built with OPC Data Client.NET or OPC Data Client-UA assemblies can also be run on 32-bit Windows, or on 64-bit Windows for x64 processors. By default, such applications run as 32-bit processes or 32-bit machines and as 64-bit processes on 64-bit machines. You can also build your code specifically for x86 or x64 platform, if you have such need.

9.11.2 Classic OPC on 64-bit Systems

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

Classic OPC is based on Microsoft COM/DCOM, which has originally been designed for 32-bit world, and later ported to and enhanced for 64-bit systems. There are several issues with COM/DCOM on 64-bit systems and some additional issues specific to OPC.

The most notable issue is the fact that browsing for OPC servers does not always fully work between 32-bit and 64-bit worlds. This is because the old OPCEnum component (provided earlier by OPC Foundation and still being installed with some servers) runs in 32-bit process and only enumerates 32-bit OPC servers. Consequently, native 64-bit OPC servers may be "invisible" for browsing from 32-bit OPC clients, although it may still be possible to connect to them, provided that the OPC client has OPC server's ProgID or CLSID.

Depending on how the OPC server registers itself, the opposite behavior is also possible: The server might be visible in the list of servers, but no connection to it possible from 64-bit processes.

Local out-of-process server (.EXE-s) are, in generable, usable across bitness boundaries (32-bit servers from 64-bit clients and vice versa), but proper setup and registration is needed (see above), which is not always the case. Local in-process servers (.DLL-s), which are relatively rare, cannot be directly used across bitness boundaries. A possible workaround is to use COM+ configuration and set them to run in a surrogate process.

Some OPC servers have a licensing approach that differentiates between local and remote usage of the OPC server, and require you to obtain a different (typically more expensive) license for the remote usage. Quite often these are 32-bit OPC servers, and their internal logic that detects the type of usage is flawed in such a way that a local usage of this 32-bit OPC server from an OPC client running in a 64-bit process is considered a "remote" usage. This results in a licensing error from the OPC server when you try to connect to it from an OPC client built with OPC Data Client and run on a 64-bit computer. It may seem that this a OPC Data Client fault, because other OPC clients work well - but that is because they are typically 32-bit clients only. The remedy is to build your OPC client for the **"x86"** target

(instead of **"AnyCPU"** or **"x64"**), or to use the **ClrFlags** tool from Microsoft to modify your executable accordingly - so that it runs as a 32-bit process.

9.12 Prerequisites Boxing

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

OPC Data Client uses “boxing”, a special technique based on file system and registry virtualization, which allows is to transparently load and use dependent software that would otherwise have to be installed (and uninstalled separately). With boxing, OPC Data Client libraries can simply be placed on disk, registered (for COM) and referenced from .NET or COM code, without installing other software.

The boxing encompasses following software:

1. Microsoft Visual C++ 2015 Redistributable (x86, x64). From Microsoft Corporation.
   Needed because parts of our software are written in managed C++ (for OPC Classic only).
2. OPC Core Components 3.00 Redistributable (x86 or x64). From OPC Foundation.
   Provides proxies/stubs that allow OPC "Classic" components to communicate, and a server enumeration facility (OPCEnum) for a discovery of OPC "Classic" servers.
3. OPC UA Certificate Generator utility.

In order to improve application startup speed, conserve memory, or in edge cases where the “boxing” approach fails, a user can still install any of the above prerequisites, and OPC Data Client will use the software installed on the disk. The download links for the individual prerequisites for such case are installed with OPC Data Client, under the Redist folder (“Redistributables” from the program group under Start menu).

9.13 Version Isolation

Different product versions can be installed on the same computer in parallel. For example, version 5.12 can be installed together with version 5.02 or even version 3.03.

The above rule only applies to the effects of the installation on the target system using the **Setup Program (Section 3.1.1)** – things like Start menu folders and shortcuts, files installed into the Program files directory, etc. As to the actual component assemblies, you can have many versions and even different builds and revisions on the same computer, and they will all work in mutual isolation.

The simulation OPC server (for OPC “Classic”) is not subject to the versioning rules described above for the OPC Data Client product. Just one instance of simulation OPC server can exist on a computer. Features are being added to the simulation OPC server with newer versions of OPC Data Client. Always install the simulation OPC server from the latest OPC Data Client version in order to guarantee that all examples are functional.

10 Best Practices

This section describes best practices that aid in developing applications and libraries that use the OPC Data Client library.

All information described in this section is merely a set of guidelines to aid development. These guidelines do not constitute an absolute truth. They are patterns that we found helpful; not rules that should be followed blindly. There are situations where certain guidelines do not apply. It is up to each individual developer to decide if a certain guideline makes sense in each specific situation.

The guidelines in this section are listed in no particular order.

10.1 Do not write any code for OPC failure recovery

As described in Failure Recovery, problems in communications with target OPC server are automatically recognized, and the component performs the recovery automatically. Attempts to duplicate this functionality in your code will interfere with this mechanism and won't work.

It is fine (and indeed, suggested) to catch the errors and handle them appropriately. But the error handling should not include attempts to remedy the situation. If you are doing "one-shot" operations (such as reads, writes etc.), it is OK to re-try them later. If you are subscribing, you should not attempt to un-subscribe in case of a problem. The component does this by itself. Making a subscription in OPC Data Client means an intent to subscribe and stay subscribed whenever possible, until you explicitly unsubscribe, and the component works in the background to fulfill this. This is avalid even if the very first (initial) subscription attempt fails; the component will keep re-trying internally, unless you unsubscribe.

In OPC Data Client-UA, you can call a static method EasyUAClient.CloseAll to close all unused sessions that are open to OPC-UA servers.

10.2 With single-operation synchronous methods, only catch OpcException or UAException

Methods that operate on a single element, e.g. an OPC Data Access or OPC XML-DA item, throw an OpcException exception for all OPC-related errors. In OPC-UA, UAException is used for the same purpose. The only other exceptions that can be thrown are program execution-related errors (such as OutOfMemoryException, or StackOverflowException), and argument validation exceptions, such as ArgumentException.

When you catch OpcException or UAException, you are completely safe that all OPC-related situations that you cannot control will be covered. This includes errors related to arguments that can only be discovered in run-time and depend on the state of environment. For example, an invalid OPC-DA item ID does not throw ArgumentException, but still an OpcException. So, even if something changes in the target OPC server, you can handle it by catching OpcException (or UAException). For more information, see Error Handling.

By catching exceptions other than OpcException (or UAException) in this case, you could improperly hide programming or catastrophic errors that should not be handled in this way.

The SubscribeXXXX and UnsubscribeXXXX methods, such as EasyDAClient.SubscribeItem, EasyDAClient.UnsubscribeItem, or EasyAEClient.SubscribeEvents, work asynchronously. This rule therefore does not apply to them; instead, see **Do not catch any exceptions with asynchronous or multiple-operation methods (Section 10.3)**.

10.3 Do not catch any exceptions with asynchronous or multiple-operation methods

Asynchronous methods (such as SubscribeXXXX), or methods that work on multiple elements at once (such as EasyDAClient.ReadMultipleItems) only throw program execution-related errors (such as OutOfMemoryException, or StackOverflowException), and argument validation exceptions, such as ArgumentException. The OPC-related exceptions are reported in a different way: By event notifications or callbacks (for asynchronous methods), or in the OperationResult.Exception properties of the methods return value array (for multiple-operation methods).

By catching exceptions in this case, you could hide programming or catastrophic errors that should not be handled in this way. For more information, see Errors and Multiple-Element Operations.

10.4 Always test the Exception property before accessing the actual result (Value, Vtq, or AttributeData property)

Whenever OPC Data Client return an OperationResult object, or an object derived from it, such as ValueResult, DAVtqResult or UAAttributeDataResult, the actual result properties are only valid when the result represents a success, i.e. its Exception property is a null reference. You should therefore always test the Exception property for null-ness first. Only the properties available in the base OperationResult class are always accessible.

The same applies to the Exception property in event notifications, for all event arguments that are derived from the OperationEventArgs class. For example, the Exception property must be checked in event handlers for the EasyDAClient.ItemChanged event (in EasyDAItemChangedEventArgs), and in event handlers for the EasyUAClient.DataChangeNotification event (in EasyUADataChangeNotificationEventArgs).

If you attempt to get other properties while OperationResult.Exception or OperationEventArgs.Exception is not null, the outcome is undefined; most likely an exception will be thrown, but that would be a serious exception indicating a programming error. For more information, see Error Handling.

10.5 Always test the HasValue property before accessing DAVtq.Value or UAAttributeData.Value

The controlling member in the DAVtq class (OPC Data Access Value/Timestamp/Quality) is the Quality property. When the quality is not sufficient, the Value property is not available (and OPC Data Client assures that is a null reference in this case). Getting the Value property when it is not available makes little sense.

The same applies to the UAAttributeData class (in OPC Unified Architecture) with regard to its StatusCode and Value properties.

It is commonly said that the value is available whenever the quality (or status code) is not Bad, but precisely speaking, this is not true, as there are some border cases (per OPC specifications) in which this rule does not apply. Your best choice is to test the HasValue property, which has the precise, OPC-compliant functionality built in. Only if HasValue is true, the Value property contains valid data.

For more information, see Data Objects.

10.6 Use multiple-operation methods instead of looping

Due to way OPC internally works, it is significantly more efficient to perform more operations at once. Whenever your application logic allows it, use methods with the word **Multiple** in their name, i.e. methods that work on multiple elements (such as OPC items) at once, and try to group together a bigger number of operations. This approach gives much better performance.

10.7 Do not block inside OPC event handlers or callback methods

You should not block for excessive or significant time inside the OPC event handlers (such as an event handler for EasyDAClient.ItemChanged) or callback methods. Doing so delays further event processing, and in serious cases, can lead to excessive memory usage and eventually loss of events.

OPC Data Client internally queues the events, and therefore any blocking in your code cannot have negative influence on the target OPC server. In the long-term, however, the average processing time for your event handlers or callback methods must be equal to or less than the average rate the OPC events are incoming.

10.8 Use generic or type-safe access wherever possible

OPC "Classic" represents data using OLE Automation VARIANT-s, which are transformed to .NET (CLR) objects. As such, a value of any type can appear in place of OPC data. Your code typically knows that certain piece of data (such as OPC item) is of specific type (such as 32-bit signed integer), and expects that the value indeed is of this type.

Instead of trying to put the type conversions and safety checks in your code, you should use the features already available in OPC Data Client.NET.

If your language supports generics and you feel comfortable working with them, it is the best choice to use generic types and generic access (see e.g. Generic Types and Generic Access). The second best choice is type-safe access, which provides similar functionality, but without use of generics (see e.g. Type-safe Access).

10.9 Use the state instead of handles to identify subscribed entities

The handles returned from any EasyXXClient.SubscribeXXXX methods are only meant for use as input arguments to other methods that manipulate the existing subscriptions – such as EasyXXClient.ChangeXXXX or EasyXXClient.UnsubscribeXXXX.

If you need to identify the subscribed entities inside event handlers, use the 'state' argument that can be passed to EasyXXClient.SubscribeXXXX methods (or a State property on XXXXArguments objects). You can pass any type of object in the state, as it is of type System.Object (and then cast the System.Object back to the original type in the event handler).

Why shouldn't the handles be used? There are multiple reasons for that:

1. The SubscribeXXXX methods are asynchronous. There is no guaranteed relation between the moment the SubscribeXXXX method returns, and the moment when events start flowing into your event handler. The events can start flowing before the methods returns. Or, they can start flowing after the method returns, but before you get a

chance to process the returned handles, and store them somewhere where the event handler can access them.
2. Similarly, UnsubscribeXXXX methods are asynchronous as well, and therefore you cannot know precisely when any event handle became invalid. You may (temporarily) receive events for a previously returned handles, even after the UnsubscribeXXXX method finishes.
3. With handles, you will need to set up and properly maintain an additional data structure – something that keeps a correspondence between the handles returned (whose values you do not know in advance), and your application data that relate to these handles. Typically, this data structure is a dictionary. Maintaining and accessing this additional data structure means extra code, and inefficient access (application data must be looked up by handle from inside the event handler).
4. Using the handles returned from SubscribeXXXX in an event handler requires coordination of the access to a data structure where the handles are stored – i.e. an inter-thread synchronization. This leads to complicated and often buggy code, with risk of deadlocks or invalid data being accessed.

All these disadvantages can simply be overcome by passing the application data needed into the SubscribeXXXX method as a state object, and then casting the State to the appropriate type and using directly inside the event handler.

Note that earlier versions passed the handle to your code in the event arguments, making it relatively easy to make a mistake of using them from inside the handler. This is no longer the case with the current version, and the likeliness of violating this best practice is therefore much lower. With extra effort, you might be able to somehow "stick" the handle into the event notification, possibly by back-filling the State property after the subscription was made. It is strongly recommended that you do not do that for the reasons explained above.

C#

```
// This example shows how to subscribe to changes of a single monitored item
// and display each change, identifying the different subscription by an
// integer.

using System;

11 Tools and Online Services

Besides offering components to integrate within your project, OPC Data Client also offers several tools and online service that can assist you in development. They include:

- **License Manager (Section 11.1)** - GUI, and **LMConsole Utility (License Manager Console) (Section 11.1.1)**
- **Connectivity Explorer (Section 11.2)**
- **The Launcher application (Section 11.3)**
- **OpcCmd Utility (Section 11.4)**
- **Demo Servers and Publishers (Section 11.5)** (some installable locally, some are online)

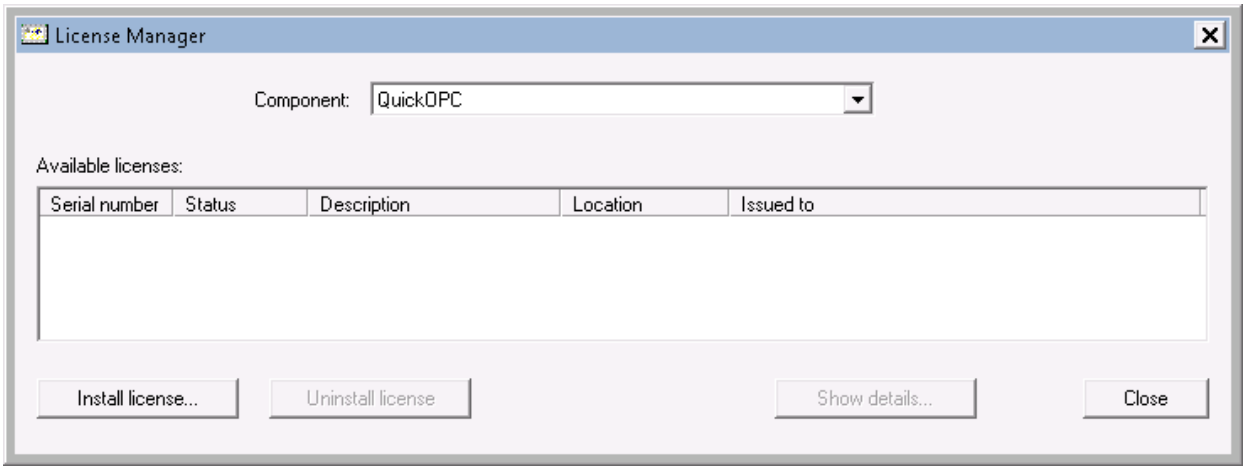
11.1 License Manager

The **License Manager** is a utility that allows you to install, view and uninstall licenses for OPC Data Client and other products which use the same licensing scheme. The **License Manager** is used:

- **On the development computer**, if you are developing on Windows and are targeting .NET Framework, COM or Excel development platform.
- **On the production (runtime) computer**, if your project is for Windows, and uses the license located in **Registry License Store (Section 8.5.2)** (as opposed to a license located e.g. in the **Managed Resource License Store (Section 8.5.1)**).

When you are targeting solely the .NET Standard development platform, you do not need to use the **License Manager** utility.

In order to install a license, invoke the License Manager application (from the Start menu or the **Launcher** application), select QuickOPC in the **Component** drop-down, and press the Install license button. Then, point the standard **Open File** dialog to the license file (typically with .BIN or .TXT extension) provided to you by your vendor.



If you have purchased some one or more of the **Product Options (Section 12)** with the base product, you may have been provided with additional license files for the product option(s). In such case, you need to install them using **License Manager** as well, under the same **Component**.

> ⚠ Note: You need administrative elevated privileges to successfully install and uninstall licenses.

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

11.1.1 LMConsole Utility (License Manager Console)

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

In This Topic

The **LMConsole** utility is a command-line equivalent of the **License Manager**, for scripting/automation (e.g. embedded installations), and folks that dislike GUIs in general. The command-line switches are described here, and a brief help is also available from the utility itself.

The utility is installed in the **Bin** subdirectory under the product folder.

Command Line Syntax

Following table summarizes the command-line switches available:

Switch	Description
-u *string* **--uninstall** *string*	Uninstall license
-s *string* **--show** *string*	Show license details
-q **--query**	Query available licenses
-l **--list**	List components
-i *string* **--install** *string*	Install licenses. The parameter is the license key file name, including extension (.BIN or .TXT, typically).
-c *string* **--component** *string*	Component name
-- **--ignore_rest**	Ignores the rest of the labeled arguments following this flag.
--version	Displays version information and exits.
-h **--help**	Displays usage information and exits.

The switches are combined to achieve the desired effect.

Typical Commands

You will typically need following LMConsole commands:

Task	Command
Query available OPC Data Client licenses	**LMConsole --component QuickOPC --query**
Install OPC Data Client license (from a file)	**LMConsole --component QuickOPC --install** *fileName*
Show OPC Data Client license details	**LMConsole --component QuickOPC --show Multipurpose**
Uninstall OPC Data Client license	**LMConsole --component QuickOPC --uninstall Multipurpose**

The license for the base product uses ID "Multipurpose". Licenses for specific **Product Options (Section 12)** have different IDs, documented with each particular product option.

Exit Codes

The LMConsole utility returns following exit codes:

Exit Code	Description
0	The command has completed successfully.
1	Command parsing error.
2	Command processing error.

11.2 Connectivity Explorer

The **Connectivity Explorer** application (for Windows only) allows the user to navigate through hierarchy of OPC Data Access and OPC Unified Architecture servers and data nodes. The user can subscribe to data changes, and view the results live.

Features of Connectivity Explorer include:

- Selected data can be transferred to Excel, where it continues to stay subscribed, giving cell values that are dynamically updated with live OPC data.
- Individual points, or a selected set of points, can be read or written to.
- Point parameters can be edited before a subscription, read or write is made.
- Multiple points can be easily subscribed to at once, using the "Bulk Add" command.
- The live view can be turned online/offline with a single push of a button.
- Single cell, or any range of cells can be copied to clipboard and pasted to other programs.
- Data can be copied to clipboard either statically, using their current value, or (for Excel) dynamically, using RTD function (see **Excel Option (Section 12.1)**).
- The currently displayed list of points can be saved to an XML file, or retrieved from a file.
- Various connectivity options can be configured, and the configuration can be in turn used when the same data is accessed by Excel.

The Connectivity Explorer uses the **Connectivity Model (Section 6.2)** as basis for its operation. Please refer to the

Connectivity Model documentation whenever necessary.

11.2.1 Main Window and Its Parts

The main window appears after the Connectivity Explorer is started. It contains three subwindows:

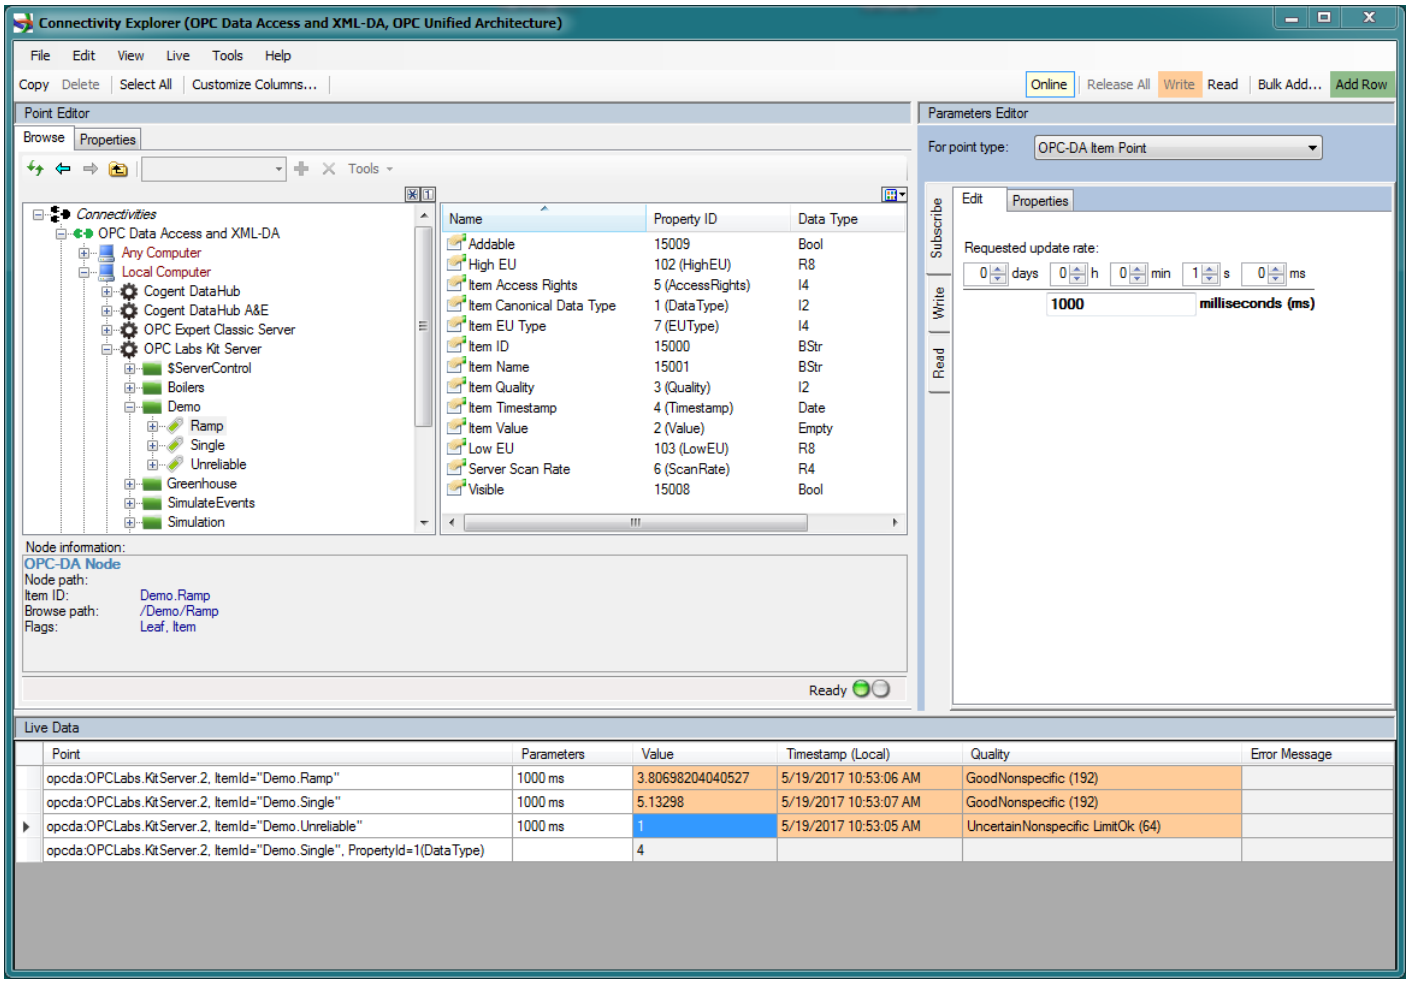
- **Point Editor (Section 6.2.3)**
- **Parameters Editor Window (Section 11.2.1.2)**
- **Live Point Data Window (Section 11.2.1.3)**

In This Topic

The usual flow of work within the Connectivity Explorer is as follows:

1. You select a point in the **Point Editor**.
2. If needed, you modify the associated parameters in the Parameters Editor.
3. Using the Add Row command (or simply by double-clicking a point in the Point Editor), you create a corresponding row in the **Live Point Data** window.
4. You observe the incoming data in the **Live Point Data** window, and possibly transfer them (using clipboard or drag-and-drop) to other applications, suich as Excel.
5. Optionally, you can also perform one-time Reads or Writes.

Below is a picture of main window, with some data already present in the **Live Point Data** subwindow.



The following articles describe the individual subwindows.

> For OPC UA, the Connectivity Explorer automatically generates its application certificate first time when it is started. This may fail if it is not running with elevated privileges ("Run as administrator"), and you may receive error message similar to "The requested key container was not found" (or other). To resolve this, run the Connectivity Explorer once with elevated privileges.

Workspace

The subwindows described above are arranged in a workspace that consists of individual cells where the subwindows can be placed. You can change the layout of the workspace in several ways:

- The splitters between the cells can be used to resize the cells.
- You can drag the cell page onto another cell and drop it there, or dock it against a border of a cell or the whole workspace. Start the drag-and-drop on the caption area of the cell page.
- Right-click on the cell page gives a context menu with commands such as Close, Close All But This, or Maximize.

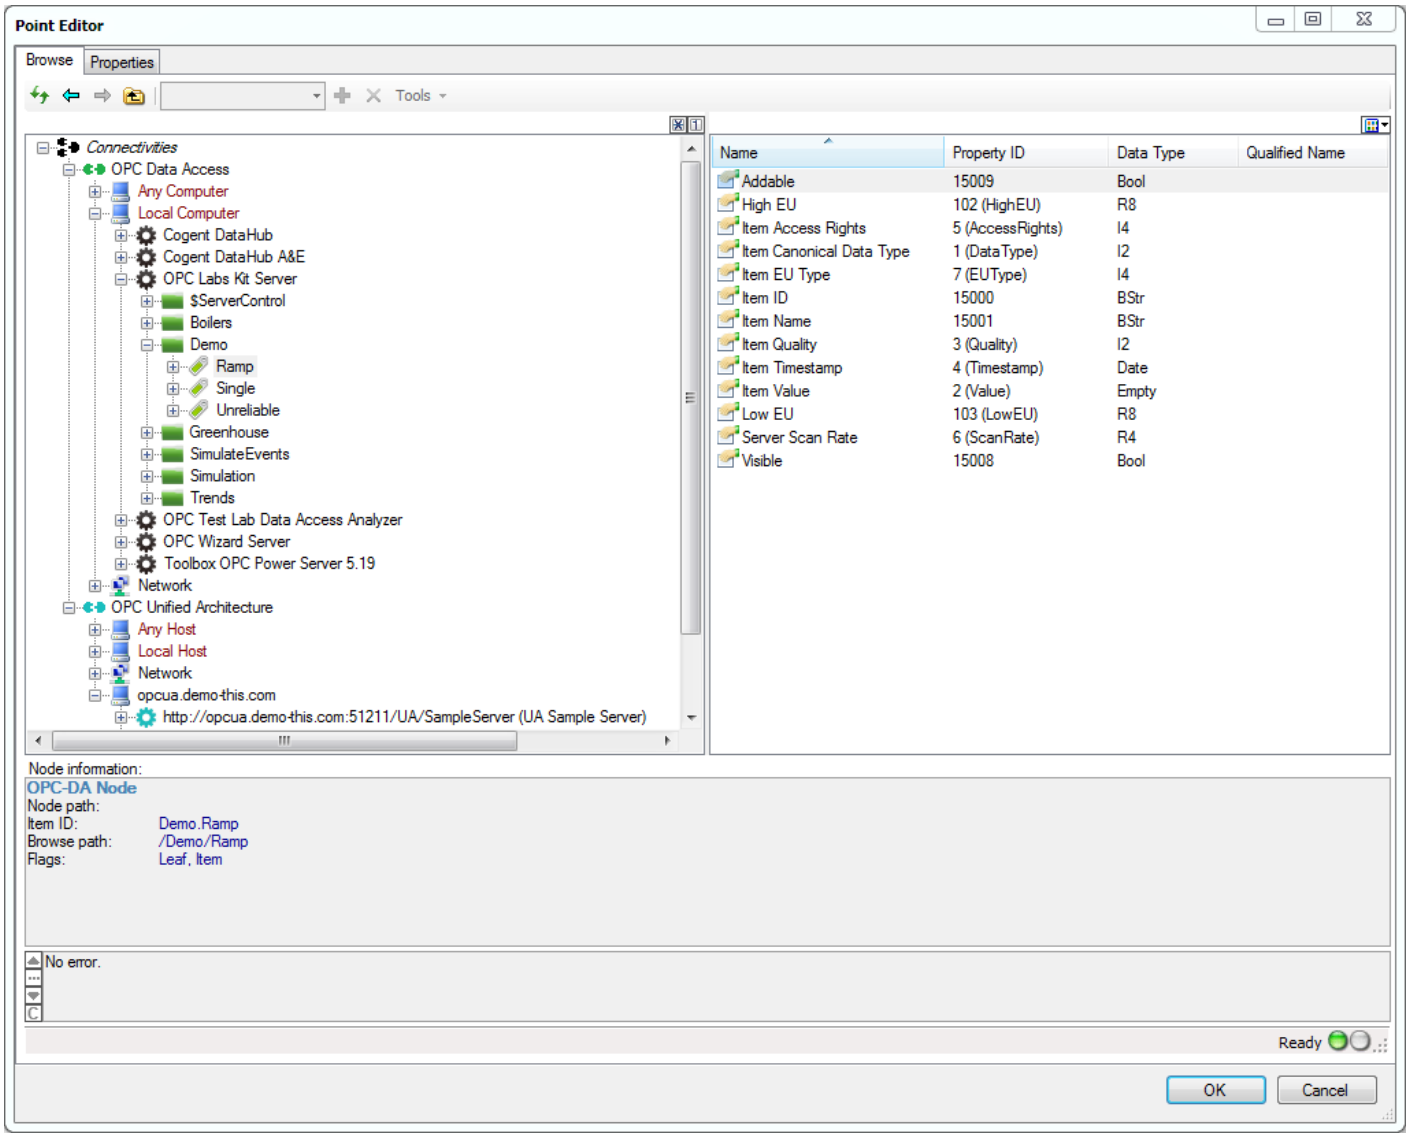
Closed subwindows can be reopened using corresponding commands on the View menu (see **Application Commands (Section 11.2.3)**).

11.2.1.1 Point Editor

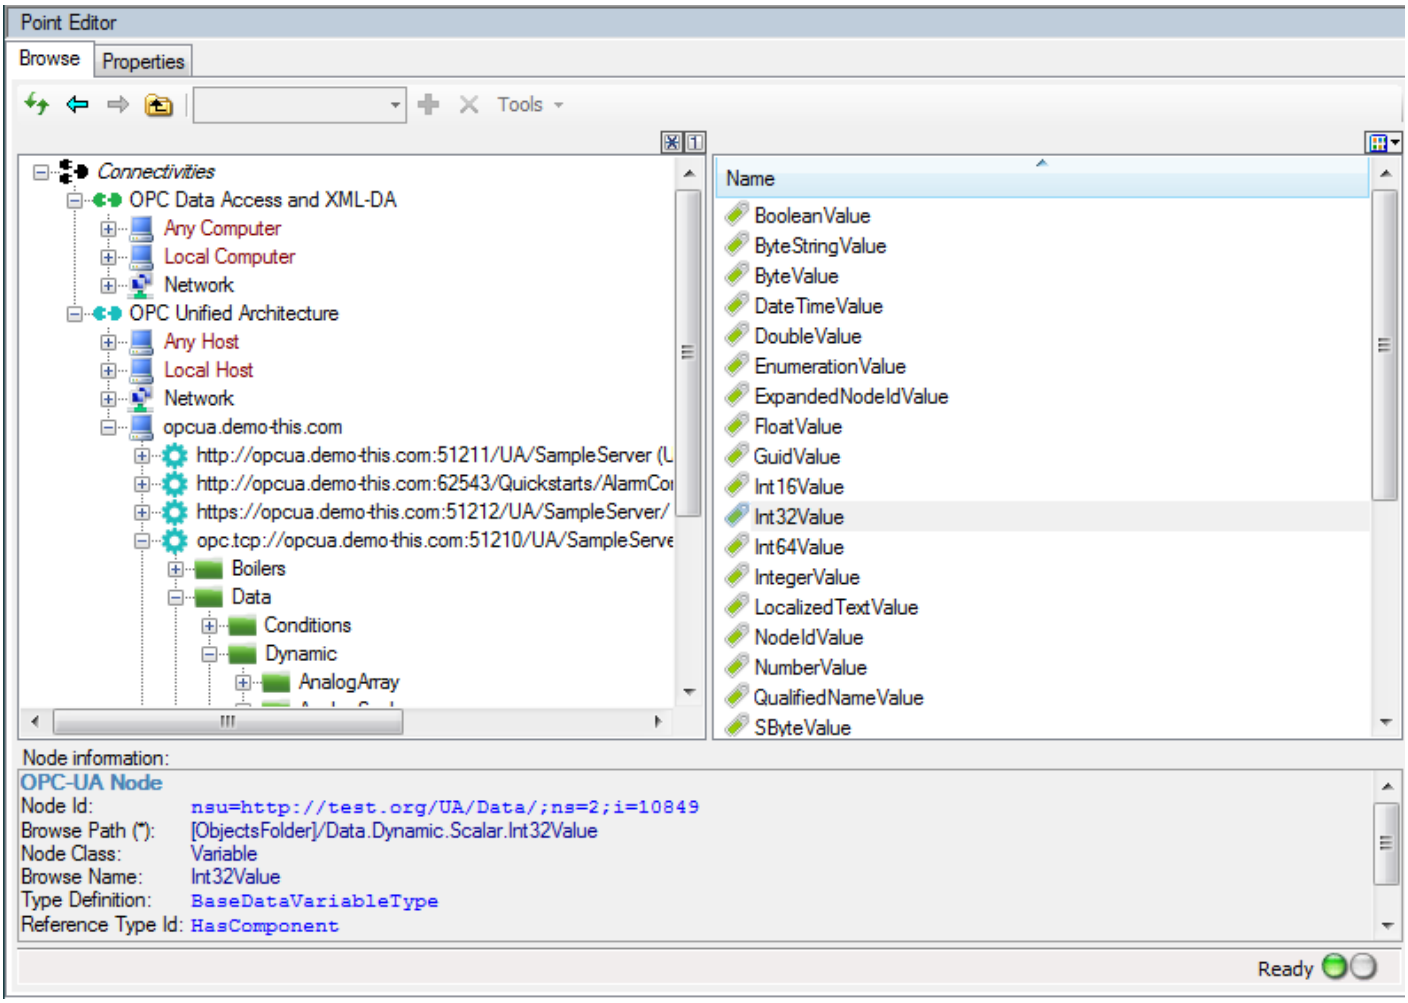
When you are working with the Connectivity Model (such as with the Live Binding in Visual Studio designer, or the Connectivity Explorer tool), you often need to specify the point you'd like to bind to or display.

For this purpose, you will use the **Point Editor**. The Point Editor can be a modal dialog (e.g. in Live Binding), or a subwindow in a larger set (as e.g. in Connectivity Explorer tool), but its main parts are always the same; what differs is the "framing".

In Live Binding, a **Point Editor** dialog is displayed. An example of it is on the following picture:



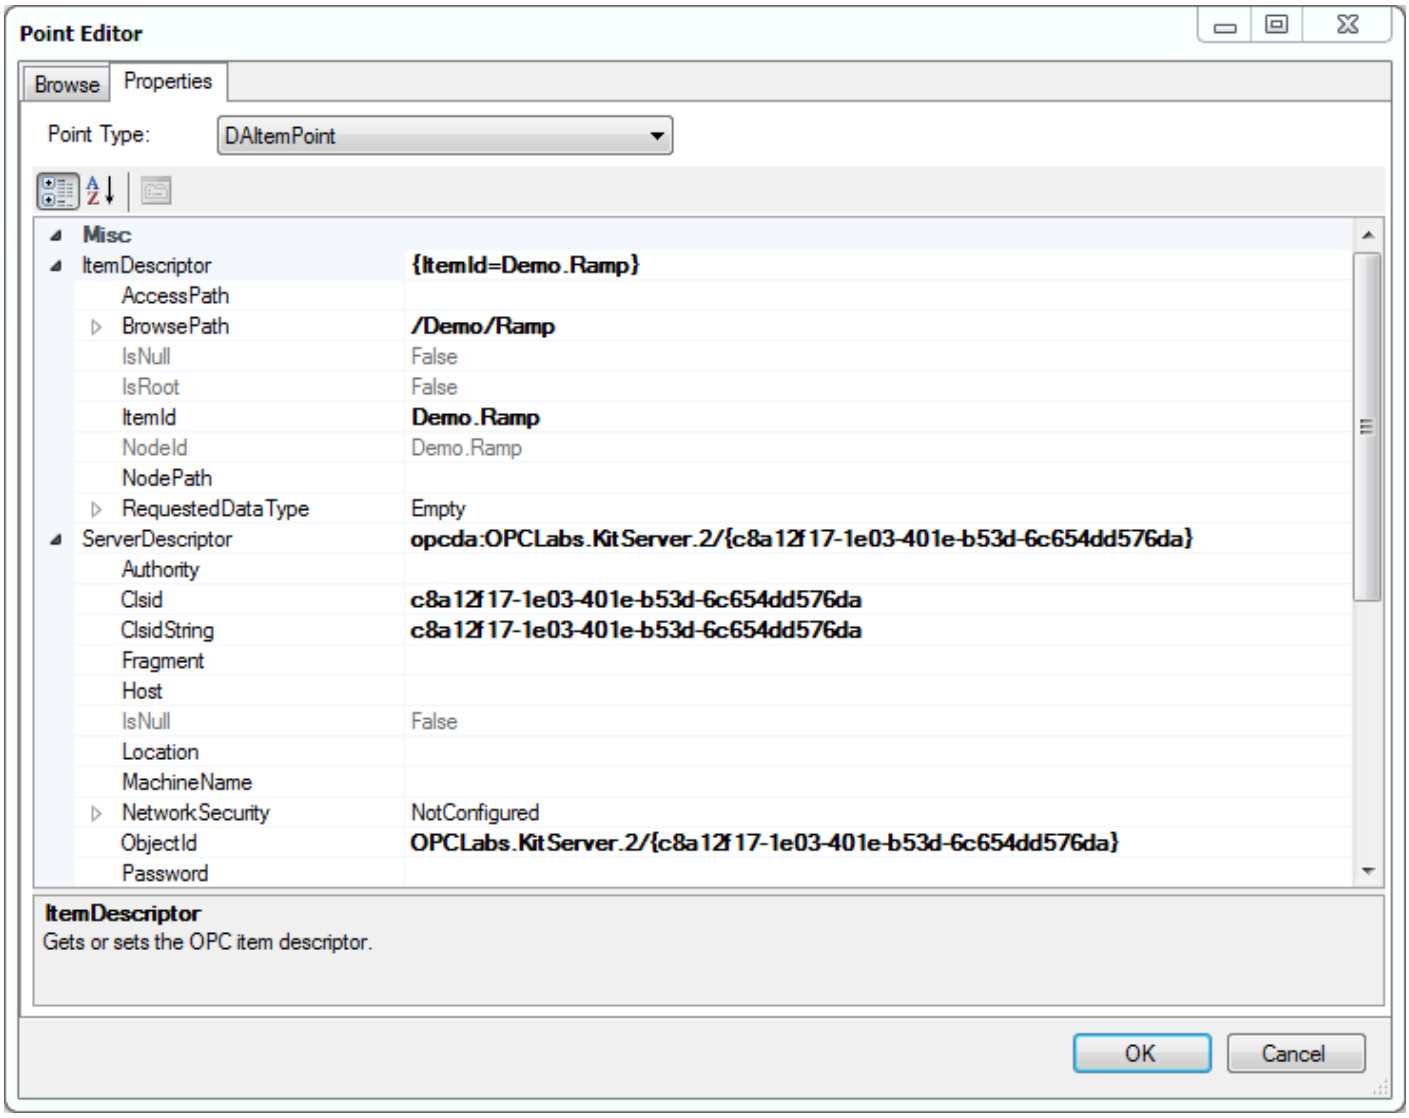
In Connectivity Explorer tool, the main window contains a **Point Editor** subwindow. An example of it is on the following picture:



The actual contents of the dialog or window will of course differ, depending on your configuration. This particular example is with a composite connectivity configured with both OPC Data Access and OPC Unified Architecture, showing multiple binding possibilities in the same dialog.

The point editor has two tabs, labeled **Browse** and **Properties**. Initially, the **Browse** tab is selected, and you are given an opportunity to browse the network, the OPC servers present, and the nodes in them. You can simply select the desired node and press OK (in Live Binding) or double-click on it (in Connectivity Explorer tool).

Sometimes the browsing is not possible, or you may need to view and possibly the details of the selected point. In such cases, you can switch to the **Properties** tab of the dialog:



In the **Properties** tab, the data that describe the point are displayed in a detailed property grid. In addition, in the upper part of the tab, you can select any type of point supported by the connectivity in use, and then fill in its properties as needed.

11.2.1.2 Parameters Editor Window

The **Parameters Editor** window allow you to specify **Parameters (Section 6.2.4)** that will be used with the (subscription) operation on the selected point. The parameters apply to the point being added to the **Live Point Data** window e.g. by the Add Row command or the Bulk Add menu command.

In This Topic

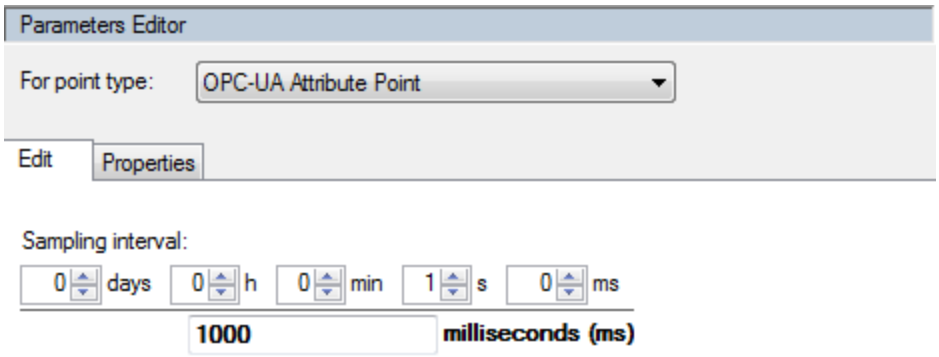
For point type

Different types of points require different parameters to be specified. This drop-down selector determines to which point type the parameters below apply. When you select a point in the **Point Editor** window, this drop-down is automatically

set for you correctly.

Edit Tab

In this tab, you can comfortably edit all or the most important parameters.

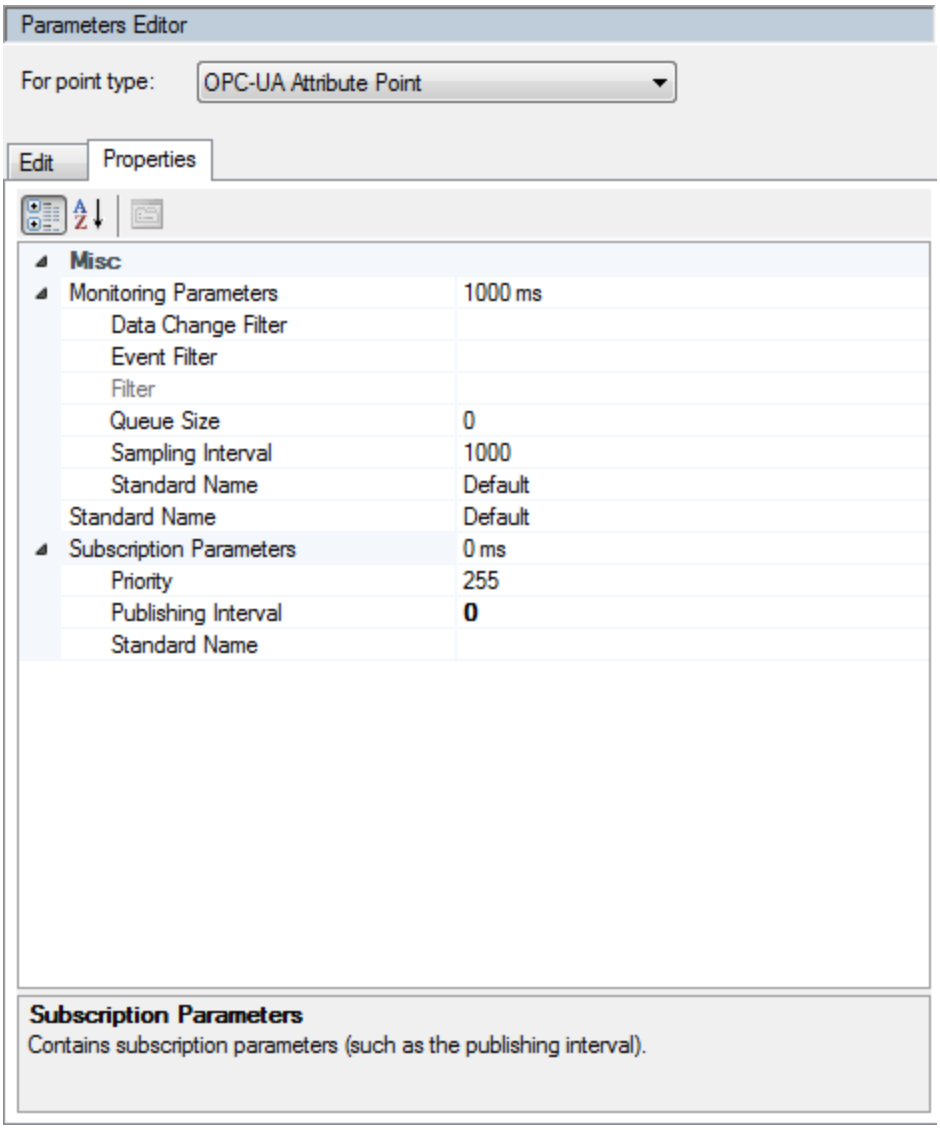


For some point types, not all parameters that exist for a point are accessible through the Edit tab. In such case, and if you need to view or change the remaining parameters, you need to switch to the **Properties** tab.

The **Edit** tab is not visible if there are no parameters to be configured for the operation on the point, or the specific point type does not support this type of parameter editing.

Properties Tab

This tab displays all configurable parameters for the operation on the point in a property grid.

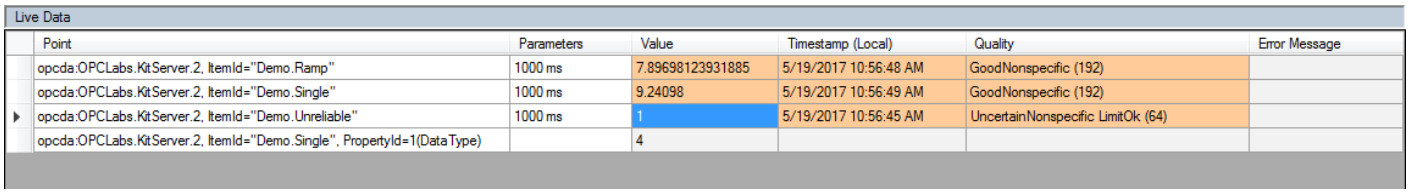


A description to the selected property is displayed in the information box at the bottom of the property grid.

11.2.1.3 Live Point Data Window

The **Live Point Data** window contains a grid, where each row represents data for a particular combination of point and parameters, and the columns represent various aspects of the data, including the value itself. You can add, remove, and modify the information contained in the grid. In addition, you can also transfer the information from the grid to other places and programs, including Excel.

In This Topic



Live Data

	Point	Parameters	Value	Timestamp (Local)	Quality	Error Message
	opcda:OPCLabs.KitServer.2, ItemId="Demo.Ramp"	1000 ms	7.89698123931885	5/19/2017 10:56:48 AM	GoodNonspecific (192)

Selecting Information

Some **Live Point Data** window commands work with a selected set of cells. The **Live Point Data** window supports a wide range of selection methods and modes, using both the mouse and the keyboard. Here are some tips:

- A single cell can be selected by clicking on it, or by navigating to it using the arrow keys on the keyboard.
- You can also use the ***Home***, ***End***, ***PageUp*** and ***PageDown*** keys for navigation.
- A whole row can be selected by clicking an empty area of the leftmost column.
- All cells can be selected by clicking an empty cell in the upper left corner of the grid.
- You can easily extend a selection to a rectangular range with a help of the ***Shift*** key.
- A non-continuous set of cells can be selected with a help of the ***Ctrl*** key.

There are also commands on the Edit menu that provide selection features.

Modifying Information

Writeable cells are visually distinguihed (by a different background color). You can navigate to the cells, and enter a new information into it. By doing so, the whole row stops displaying the information from Subscribe, and changes the font to ***bold italic***. After you have modified the cells you want, you can use the Write command (***Ctrl+W***) to perform a Write operation on all rows that in Write state.

Use the Release (***Esc***) or Release All command to revert the current row, or all rows, back to normal state. This is done either because you have changed your mind and do not want to write the row(s), or after you have viewed the results of the last Write operation and want to switch back to receiving updates from Subscribe.

Viewing Information

You can resize columns by dragging in the area of the vertical divider lines between them.

Commands

For information about the available commands, see **Live Point Data Commands (Section 11.2.1.3.1)**. The commands can be invoked e.g.

- From the main application menu.
- From the main application toolbar.
- From the **Live Point Data** context menu, accessible by right mouse click in the **Live Point Data** window area, or by pressing the ***Menu*** key when the window is focused.
- By keyboard shortcuts.

11.2.1.3.1 Live Point Data Commands

In This Topic

Edit Menu

Copy Command

Copies the contents of the selected cells to clipboard. See **Options Command (Section 11.2.3.1)** for settings that influence how the copy is done. For example, dynamic cells can be copied in such a way that they continue showing dynamic information from the data source after being pasted to Excel.

You can also use ***Ctrl+C*** to invoke this command.

Delete Command

Deletes the selected rows from the grid. You can also use ***Del*** to invoke this command.

Select All Command

Selects all cells in the grid. You can also use ***Ctrl+A*** to invoke this command.

Select None Command

Empties the selection set in the grid. You can also use ***Ctrl+N*** to invoke this command.

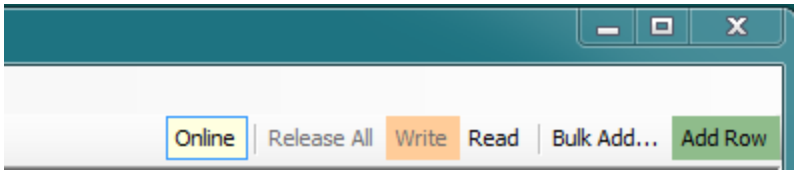
View Menu

Customize Columns Command

The **Customize Columns** command allows you influence which columns are displayed in the grid, which information they contain and how they look like. For details, see **Customize Columns Command (Section 11.2.1.3.1.1)**.

Live Menu

Commands under this menu allow you to control what gets displayed in the **Live Point Data** window. For easy access, they are also grouped as toolbar buttons near the upper right corner of the main window.



Add Row Command

Adds a new row to the **Live Point Data** window, for point selected in the Point Editor Window and with parameters selected in the **Parameters Editor Window (Section 11.2.1.2)**. The command also automatically determines the columns needed to display the relevant aspects of the data, and adds missing columns to the **Live Point Data** grid as

necessary.

The command is disabled when no point is selected in the **Point Editor** window.

Bulk Add Command

This command allows you to add many points at once. It invokes a point selection dialog with multi-select ability. Make your selection, and accept it in the dialog. All selected points will be added to the **Live Point Data** window. Each point will use parameters from the **Parameters Editor** window that correspond to its type.

Read Command

This command performs a Read operation on all currently selected rows (or rows that contain any selected cells, including the current cell). The Read is perfomed with parameters that are currently set for it in the **Parameters Editor** window.

Each row that was read stops displaying the information from Subscribe, and changes the font to **bold**. Use the Release (***Esc***) or Release All command to revert the current row, or all rows, back to normal state. This is done after you have viewed the results of the last Read operation and want to switch back to receiving updates from Subscribe.

You can also use ***Ctrl+R*** to invoke this command.

Write Command

This command performs a Write operation on all rows that are currently in a Write state (as indicated by ***bold italic*** font). A row enters the Write state when you start typing into any writable cell of it.

You can also use ***Ctrl+W*** to invoke this command.

The values you enter are, by default, parsed (evalued) before they are actually written. To configure this behavior differently, use the **Options Command (Section 11.2.3.1)**.

Release Command

Reverts the currently selected rows (or rows that contain any selected cells, including the current cell) back to the normal state, in which they display Subscribe updates.

Release All Command

Reverts all rows back to the normal state, in which they display Subscribe updates. You can also use ***Ctrl+E*** to invoke this command.

Online Command

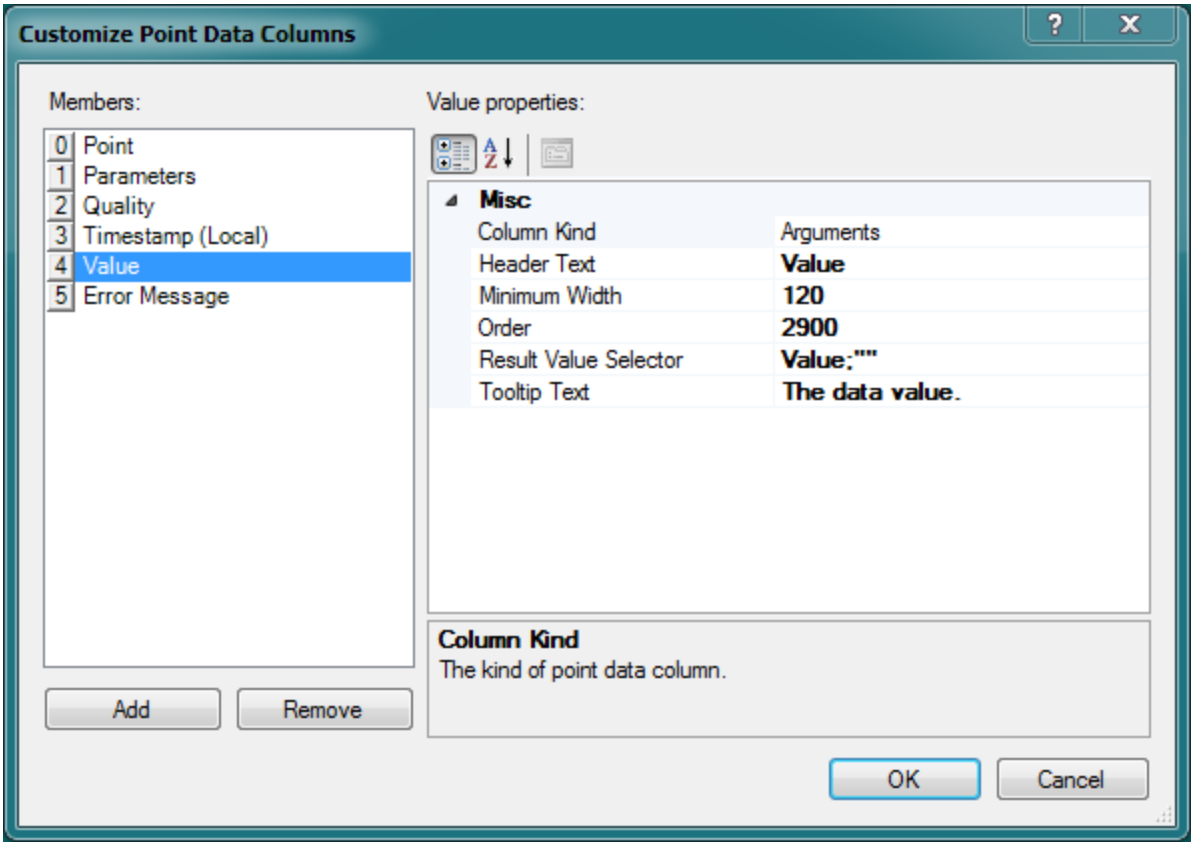
This is a toggle command. In the "on" state (online), the **Live Point Data** window is connected to the data source, and shows live data. Subscriptions are performed in order to obtain the data from the data source. In the "off" state (offline). the **Live Point Data** window is not connected to the data source, and the latest obtained values are shown.

You can also use ***Ctrl+L*** to invoke this command.

> ⚠ The **Online** command does not influence the **Point Editor** window. It is therefore possible to make connections and browse the data in the **Point Editor** even when the status is "offline".

11.2.1.3.1.1 Customize Columns Command

The **Customize Columns** command allows you influence which columns are displayed in the grid, which information they contain and how they look like. The command invokes a **Customize Point Data Columns** dialog:



The list on the left contains the columns that are currently displayed in the grid. By selecting a column from this list, you can view and edit its properties in the grid on the right side of the dialog. You can also add and remove columns.

Most properties are self-explanatory, and there is also a description in the box below the property grid. Besides many properties that influence *how* the information will be shown, there are two important ones that dictate *what* will be shown: Column Kind and Result Value Selector.

Column Kind Property

Selects where the information in the column comes from. It can be:

- **Point**: Information about the point in the data source that is being addressed.
- **Parameters**: Information about the parameters associated with the operation on the point.
- **Arguments**: Specific arguments of the operation - typically, its outputs.

Result Value Selector Property

Determines the specific piece (or pieces) of information that will be extracted and displayed. For details, see **Result Value Selector (Section 11.2.2)**.

11.2.2 Result Value Selector

In This Topic

The **Result Value Selector** is a text string that determines the specific piece (or pieces) of information that will be extracted and displayed from a target object.

The result value selector can have one of two forms:

```
successAndFailureElementPath
```

or

```
successElementPath ; failureElementPath
```

where

- *successAndFailureElementPath* is an element path in the target object that will be used regardless of whether the operation has succeeded or failed.
- *successElementPath* is an element path in the target object that will be used when the operation has succeeded.
- *failureElementPath* is an element path in the target object that will be used when the operation has failed.

In the second case, the elements paths are separated by a semicolon.

> When used for defining columns, the *failureElementPath* is only effective when the **Column Kind** is set to **Arguments** (and not to other kinds such as **Point** or **Parameters**).

Each element path can be either

- Empty. In this case, the target object as such will be the result of the extraction.
- A string constant, enclosed in doublequotes. The string will become the extracted value.
- A name of a property of the target object, optionally followed by names of sub-properties and so forth; the names are separated by dots. A value of the selected property (or its subproperty) will be extracted.

The types of target objects (point, parameters, and arguments), and therefore the names and meaning of their properties, can be found in **Point Types Reference (Section 16.5)**.

Examples

Always extract the **ErrorMessage** property from the target object:

```
ErrorMessage
```

Always extract the **Value** property from the target object:

```
Value
```

Extract the **Value** property from the target object when the operation succeeded; return an empty string when the operation has failed:

```
Value;""
```

Extract the **Value** property from the target object when the operation succeeded; return "N/A" when the operation has failed:

```
Value;"N/A"
```

Extract the **Value** property from the target object when the operation succeeded; extract the **ErrorMessage** property when the operation has failed:

```
Value;ErrorMessage
```

Extract the **Vtq** property (OPC-DA) from the target object when the operation succeeded; extract the **ErrorMessage** property when the operation has failed:

```
Vtq;ErrorMessage
```

Extract the **AttributeData** property (OPC-UA) from the target object when the operation succeeded; extract the **ErrorMessage** property when the operation has failed:

```
AttributeData;ErrorMessage
```

11.2.3 Application Commands

This article describes Connectivity Explorer commands that are not related to any specific window.

In This Topic

File Menu Commands

New Command

Clears (removes) any existing rows in the **Live Point Data** window.

You will be prompted to save any modified unsaved data, if needed.

Open Command

Allows you to retrieve a previously saved data (row definitions in the **Live Point Data** window) from an XML file. You can also use ***Ctrl+O*** to use this command.

You will be prompted to save any modified unsaved data, if needed.

Insert From Command

Allows you to add previously saved data (row definitions) to the current data in the **Live Point Data** window.

Save Command

Saves the current data (row definitions in the **Live Point Data** window) into an XML file. It uses the name of the file from the last Save As or Open; it asks for the file name in case none is known yet.

You can also use ***Ctrl+S*** to invoke this command.

Save As Command

Asks you for a name of the file, and saves the current data (row definitions in the **Live Point Data** window) into an XML

file. The selected file will then be used in subsequent Save commands automatically.

Exit Command

Closes the main window and exits the application. The selected options and connectivity configuration are preserved between subsequent runs of the application. You can also use ***Alt+F4*** to invoke this command.

You will be prompted to save any modified unsaved data, if needed.

View Menu Commands

Point Editor Command

Opens and selects the **Point Editor (Section 6.2.3)** window, or simply selects it if it is already open.

Parameters Editor Command

Opens and selects the **Parameters Editor Window (Section 11.2.1.2)**, or simply selects it if it is already open.

Live Point Data Command

Opens and selects the **Live Point Data Window (Section 11.2.1.3)**, or simply selects it if it is already open.

Event Records Command

Opens a window that allows you to view the event records generated by the application.

Currently, only operations of the "OPC Unified Architecture" connectivity generate event records.

Tools Menu Commands

Options Command

The **Options** command allows you to specify options for the application, i.e. configure the environment to your needs. For details, see **Options Command (Section 11.2.3.1)**.

Configure Connectivity Command

The **Configure Connectivity** command allows you to view and modify various setting that influence how the application connects to its data sources. For details, see **Configure Connectivity Command (Section 11.2.3.2)**.

Windows Menu Commands

Reset Windows Layout Command

Restores the application windows back to their original structure.

Help Menu Commands

Contents Command

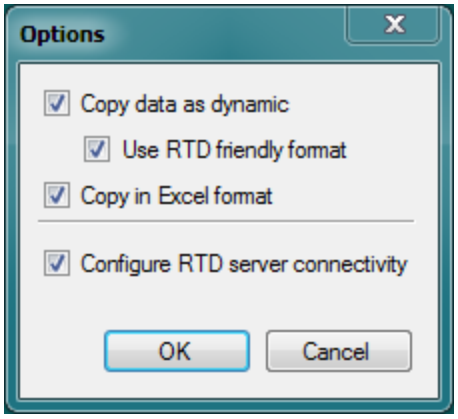
Opens a Web browser window (using your default browser) with online documentation to the application. You can also use ***F1*** to invoke this command.

About Command

Display a dialog box with information about the application, its purpose, version, and intellectual property-related matters.

11.2.3.1 Options Command

The **Options** command allows you to specify options for the application, i.e. configure the environment to your needs. The selected options are preserved between subsequent runs of the application.



Parse entered values

Determines whether the entered values will be parsed before use.

When this setting is turned off: The values are written as entered.

When this setting is turned on: If the entered value does not start with "{", it is written "as is", as a scalar. If the entered value starts with "{", it is considered an array, it must end with "}" and contain a list of elements separated by ",". For example, to write an integer array, enter ***{1,2,3}***. To write a string array, enter ***{abc,def,ghi}***. No provision is made for escaping the special cases yet.

Copy data as dynamic

When the **Copy data as dynamic** box in the **Options** dialog in **Connectivity Explorer** is checked, dynamic data transferred from the Connectivity Explorer through clipboard or drag-and-drop are transformed into RTD function calls, which allows them to remain dynamic when used in Excel.

When this box not checked, dynamic data transferred from the Connectivity Explorer simply contains their current value, static.

Use RTD friendly format

When the **Use RTD friendly format** box in the **Options** dialog in **Connectivity Explorer** is checked, and when the actual point and parameters used allow it, the generated RTD function calls use a friendly topic format, which is easier to read

and modify by a human. The friendly format uses a short series of arguments as topic strings in the RTD function.

When this box is not checked (or when the actual point and parameters used cannot be expressed in the friendly format), the generated RTD function call will specify the topic strings using XML (more lengthy, and less readable).

Copy in Excel format

When the **Copy in Excel format** box in the **Options** dialog in **Connectivity Explorer** is checked, (static) data transferred from the Connectivity Explorer through clipboard or drag-and-drop are formatted with Excel in mind. This setting tries to bypass some Excel "intelligence" that causes incorrect data imports.

Some examples of what this settings is trying to do:

- Prevent Excel from interpreting strings that begin with plus or minus sign, a decimal point, or a digit, as numbers.
- Prevent Excel from interpreting strings that "look like" dates or times as being actual dates or times.
- Assure proper transfer of Boolean values.
- Assure that date and time values will be transferred without misinterpretation, independent of any language or regional settings.
- Assure that time values do not lose milliseconds or even seconds.
- Assure that date and time values will be formatted by Excel as such.

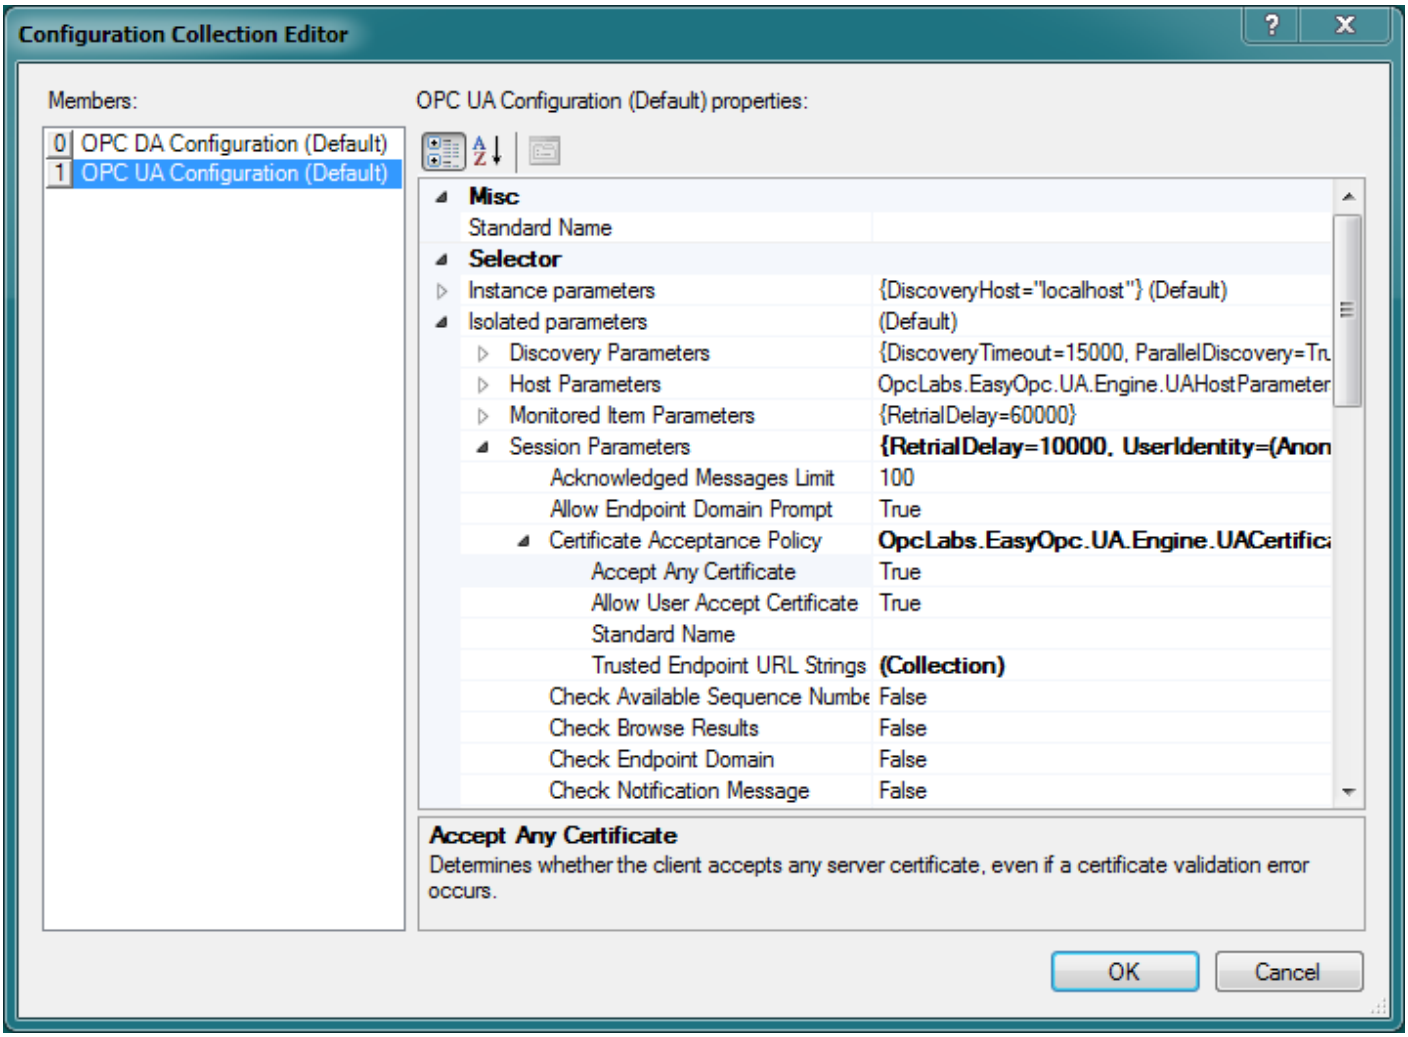
Uncheck this box if you need to transfer data to programs other than Excel.

Configure RTD server connectivity

When the **Configure RTD server connectivity** box in the **Options** dialog in **Connectivity Explorer** checked, any changes you make to the connectivity cofiguration (see **Configure Connectivity Command (Section 11.2.3.2)**) are also saved for use by the Connectivity RTD Server. This assures that your Excel spreadsheets with the RTD functions will use the same connectivity configuration as the one in the Connectivity Explorer. Note that you may have to restart Excel in order for any setting changes to take effect.

11.2.3.2 Configure Connectivity Command

The **Configure Connectivity** command allows you to views and modify various setting that influence how the application connects to its data sources. The connectivity configuration is preserved between subsequent runs of the application.



There is one group of configuration settings for OPC Data Access and XML-DA, and a separate group for OPC Unified Architecture. Each setting is briefly explained in the information box below the property grid. You will find further explanation to some settings elsewhere in this documentation, including the Reference part for the corresponding types.

In some cases (typically, after changing some value under Shared Parameters), you may be prompted to restart the application, so that the configuration changes can take effect.

If the **Configure RTD server connectivity** box is checked in the **Options** dialog (see **Options Command (Section 11.2.3.1)**), any connectivity configuration changes that you make will also be taken over by the RTD server, i.e. by the Excel worksheets that reference dynamic data using the RTD function.

The default settings are tuned for high interoperability.

For OPC UA, if you need settings that are tuned for best OPC compliance, select the OPC UA Configuration member, and then, in the property grid, click on the drop-down arrow next to the Standard Name, and select the OpcCompliance value from the list.

The default settings for OPC Unified Architecture allow (and prefer) non-secure connections. Therefore, a non-secure connection is made if the target OPC server has an endpoint that supports that.

You can change this behavior as follows:

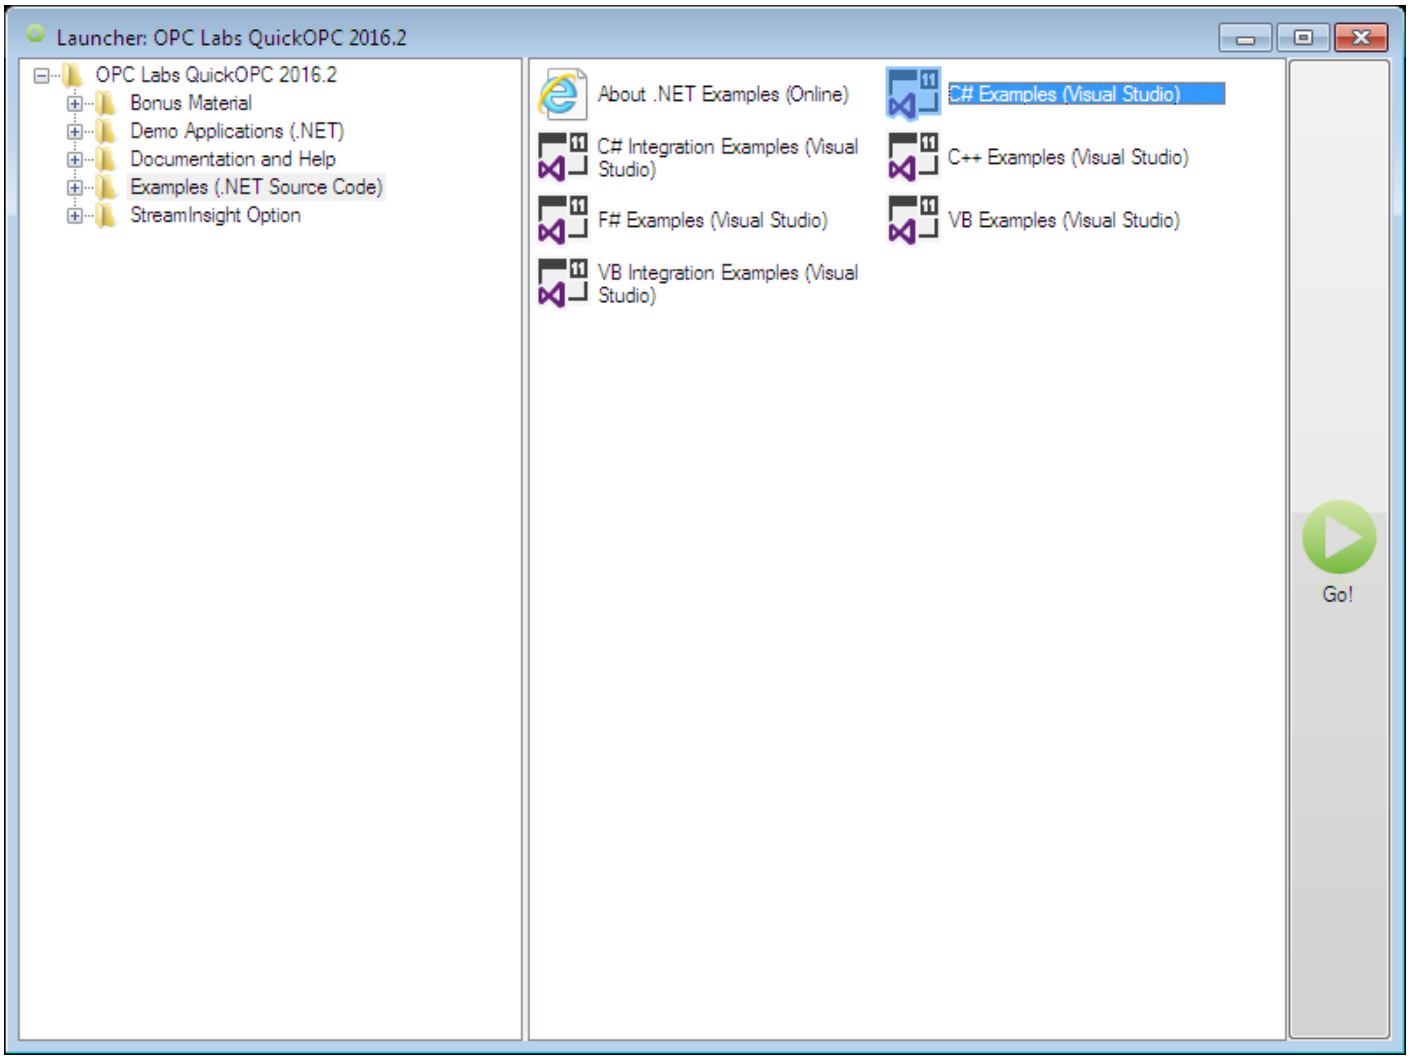
1. In the list on the left side, select the OPC UA Configuration member.
2. In the Selector category, expand the Isolated Parameters item, then expand the Session Parameters item, and then expand the Endpoint Selection Policy item.
3. Choose which security modes will be allowed: Click on the drop-down arrow next to the Allowed Message Security Modes, and select a combination of the modes. For example, for all modes except non-secure connections, make sure that Secure is checked, and SecurityNone is unchecked.
4. If both secure and non-secure modes are allowed (and available from the server), you may choose whether the secure or non-secure mode will be preferred: Click on the drop-down arrow next to the Message Security Preference, and select Negative to prefer the non-secure mode, None for no particular preference, or Positive to prefer the secure modes.

Note that if you select OpcCompliance for the Standard Name on Endpoint Selection Policy or higher in the hierarchy, the secure modes will be preferred, but non-secure mode will still be allowed.

11.3 The Launcher application

The Launcher application is a switchboard that presents the same shortcuts as those available from the Start menu. It serves as a starting point for work with QuickOPC. In addition, for users of Windows 8 and later, it allows them to easily navigate the various QuickOPC shortcuts, as the Start menu in Windows 8 and later is essentially broken for applications that install a hierarchical structure of shortcuts.

The Launcher is only available on Windows, when OPC Data Client has been installed with the **Setup Program (Section 3.1.1)**.



The Launcher application is also accessible from a desktop shortcut, from the Programs group (Start menu), and from the Quick Launch bar (note that Quick Launch isn't visible by default; to enable it, see https://support.microsoft.com/en-us/kb/975784).

You can use the tree on the left side to select a group of actions you are interested in, and then view the actions in the list on the right side. You can launch any action by double-clicking on its icon, or by selecting it first and then pressing the "Go!" button.

11.4 OpcCmd Utility

The **OpcCmd** utility is a program that allows performing various OPC operations from the command line. It can act as a generic OPC UA PubSub subscriber, and be used for evaluation, experiments, and testing.

For more information, see:

- Using OpcCmd Utility as OPC UA PubSub Subscriber
- Category:OpcCmd

11.5 Demo Servers and Publishers

To demonstrate capabilities of OPC Data Client, some OPC server (or publisher, for PubSub) is needed. One such server ships with the product, and more are made available remotely (online).

For OPC Classic (COM/DCOM-based):

- **Simulation Server for OPC Classic (Section 11.5.1)**

For OPC XML:

- **OPC XML Sample Server (Section 11.5.2)**

For OPC UA (Unified Architecture):

- **OPC UA Sample Server (Section 11.5.3)**
- **QuickStart Alarm Condition Server (OPC UA) (Section 11.5.4)**

For OPC UA PubSub:

- **OPC UA Demo Publisher (Section 11.5.5)**

11.5.1 Simulation Server for OPC Classic

The demo application installed with the product, and most examples use an OPC Simulation Server that is installed together with OPC Data Client. The server's ProgID is **"OPCLabs.KitServer.2"**.

The demo application and the examples are designed to connect to the Simulation OPC Server in its default configuration (i.e. as shipped). In fact, some very simple examples connect to just one OPC item, named **"Demo.Ramp"**. There are various other OPC items in this server that you can use in your own experiments too.

Note 1: When OPC proxies/stubs are not installed on the system, the installation program installs them together with the simulation server.

Note 2: On 64-bit platforms, the installation program still registers the 32-bit (x86) binary of Simulation OPC Server. This configuration gives better OPC compatibility. The 64-bit binary of Simulation OPC Server is also installed to the disk, and can be registered manually if needed.

This functionality is not available under (or the text does not apply to) .NET Standard development platform.

11.5.2 OPC XML Sample Server

The OPC XML Sample Server is not installed with the product, but is made available on the Internet. You can use it for your explorations and tests. The server's URL is http://opcxml.demo-this.com/XmlDaSampleServer/Service.asmx . Our example code also refers to this server, so that the examples can be run without having to set up a server locally.

The server is based on the sample server code from OPC Foundation. It provides some OPC data of its own, and it wraps two OPC COM-based servers (OPC-DA 2.0 and OPC-DA 3.0). It contains a combination of items of various data types, static and dynamic, some readable and some also writeable.

OPC XML does not define a way for server discovery (browsing for servers). For this reason, if you are using user interface components such as the browsing dialogs or controls, you need to specify the server manually, using its URL.

> You are only licensed to use this online service with connections made from OPC Data Client, and not from any other software. Also, please do not use it for any kind of load or volume testing or tests that require substantial computing or network resources (such as subscribing to many variables at once), because that could have negative impact on other users, and on our ability to provide this online service. We reserve the right to deny access to online services when we detect that these conditions has not been followed.

11.5.3 OPC UA Sample Server

To demonstrate capabilities of OPC Data Client, some OPC server is needed. Most examples use an OPC UA Sample Server provide by OPC Labs (based on OPC Foundation sample server) that is available over Internet. The server can be accessed on opc.tcp://opcua.demo-this.com:51210/UA/SampleServer, http://opcua.demo-this.com:51211/UA/SampleServer or https://opcua.demo-this.com:51212/UA/SampleServer (these are so-called Discovery URIs).

Note that if there is a firewall between the client machine and the server, it needs to have the corresponding ports (in the above example, 51210, 51211 and 51212) open for outbound traffic.

The demo application and the examples are designed to connect to the OPC UA Sample Server in its default configuration. In fact, some very simple examples connect to just one OPC node. For example, a dynamically changing double-precision value has node Id **"nsu=http://test.org/UA/Data/;i=10854"**. You can either call the browsing methods to obtain other node Ids together with their descriptions, or you can simply borrow the node Ids used in our examples. There are various other OPC nodes in this server that you can use in your own experiments too.

> You are only licensed to use this online service with connections made from OPC Data Client, and not from any other software. Also, please do not use it for any kind of load or volume testing or tests that require substantial computing or network resources (such as subscribing to many variables at once), because that could have negative impact on other users, and on our ability to provide this online service. We reserve the right to deny access to online services when we detect that these conditions has not been followed.

11.5.4 QuickStart Alarm Condition Server (OPC UA)

We run a public Quickstart Alarm Condition Server (OPC UA) that you can use for your explorations and tests. The server is located on **opcua.demo-this.com**, and its endpoint URLs are:

- **opc.tcp://opcua.demo-this.com:62544/Quickstarts/AlarmConditionServer**
- http://opcua.demo-this.com:62543/Quickstarts/AlarmConditionServer

Our example code also refers to this server, so that the examples can be run without having to set up a server locally.

The server is based on the code from OPC Foundation.

> You are only licensed to use this online service with connections made from OPC Data Client, and not from any other software. Also, please do not use it for any kind of load or volume testing or tests that require substantial computing or network resources (such as subscribing to many variables at once), because that could have negative impact on other users, and on our ability to provide this online service. We reserve the right to deny access to online services when we detect that these conditions has not been followed.

11.5.5 OPC UA Demo Publisher

The **OPC UA Demo Publisher** is useful for demonstrating OPC UA PubSub. It is the publisher that we use in most of our examples for OPC UA PubSub.

For more information, see:

- UADemoPublisher Basics
- Category:UADemoPublisher

11.6 Test Tools

OPC Data Client ships with certain internal testing tools that might be of interest to advanced users, and were created partially in relation to OPC compliance certification process.

The test tools are not installed by default; you need to select “Custom Install”, and then specifically enable them on the “Select Components” page in the installation wizards. After installation, the test tools can be reached through the Start menu or the Launcher application, in the “Test Tools” group.

There is a separate document (online) that contains the list of test tools, their purpose, and instructions on how to operate the tools. When the Test Tools are installed, you can access it from the Start menu as well.

12 Product Options

12.1 Excel Option

Microsoft, MSDN, Excel, Windows, and Windows Server are trademarks of the Microsoft group of companies.
All other trademarks are property of their respective owners.

12.1.1 Introduction to Excel Option

With the Excel Option for OPC Data Client, you can set up a communication link between Excel and any OPC server. It is possible to subscribe to and view real-time data, and also write the data back.

OPC Classic, OPC XML and OPC UA servers are supported. No programming, macros or add-ins are necessary.

This functionality is not yet available for OPC UA PubSub.

In This Topic

Supported Excel Versions

The OPC Data Client Excel Option supports following Excel versions:

- Excel 2016 (32- and 64-bit)
- Excel 2013 (32- and 64-bit)
- Excel 2010 (32- and 64-bit)
- Excel 2007 (32- and 64-bit)

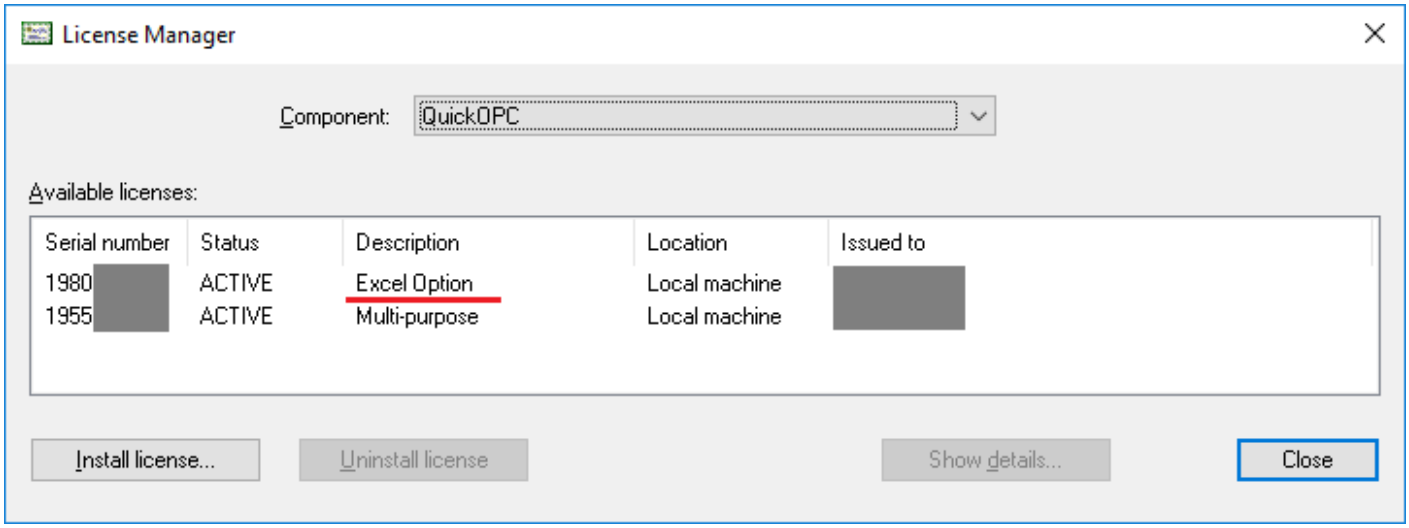
Excel 2003 may also work, but we have not tested with it and do not officially support it.

Note that Excel 2003, Excel 2007 and Excel 2010 are no longer on mainstream support by Microsoft.

Licensing

Excel Option is usually licensed separately from the base product, and in such case you will receive a separate license file for the Excel Option. See **License Manager (Section 11.1)** for more information.

The license is shown with Description "Excel Option". Its ID for use with the **LMConsole Utility (License Manager Console) (Section 11.1.1)** is "ExcelOption". When properly installed, you will have two licenses under the "QuickOPC" component name in License Manager, and the form will look similar to this:



If you are running the trial license, Excel Option is automatically included (enabled), with 30-minute runtime limitation per

each process (Excel) run.

12.1.2 Getting Started under Excel

OPC Data Client allows you to develop Excel spreadsheets that contain values and formulas that are dynamically updated from OPC data, without any programming.

In This Topic

Making a first real-time Excel spreadsheet

In this Getting Started procedure, we will create am Excel spreadsheet that subscribes to OPC Data Access (OPC DA) item or OPC Unified Architecture (OPC UA) node, and continuously displays it changes. With OPC Data Client., this can be achieved without any coding, and also without installing any Excel add-ins, only with help of so-called RTD server component that comes with OPC Data Client.

1. Install OPC Data Client. Make sure that you have selected an installation choice that includes Excel integration.
2. Start Microsoft Excel and create a new blank workbook.
3. From Windows Start menu, navigate to OPC Data Client 2020.2 Launcher, and run it.
4. In the **Launcher** application (when the root node is selected in the tree on the left side, which is the default state), select the Connectivity Explorer icon in the list on the right side, and press the green Go! button. Alternatively, simply double-click on the Connectivity Explorer icon.
5. In the **Connectivity Explorer** application, locate the **Point Editor** sub-window, and select a "point" to subscribe to, using one of the procedures described below.
   a. For OPC Data Access (OPC DA), on the **Browse** tab, navigate in the tree (on the left) to Connectivities -> OPC Data Access and XML-DA -> Local Computer -> OPC Labs Kit Server -> Demo -> Ramp.
   b. For OPC Unified Architecture (OPC UA), on the **Browse** tab, navigate in the tree (on the left) to Connectivites -> OPC Unified Architecture -> opcua.demo-this.com -> http:// opcua.demo-this.com:51211/UA/Sample Server (UA Sample Server) -> Data -> Dynamic -> Scalar -> DoubleValue.
6. Press the dark green Add Row button on the main toolbar (near the upper right corner of the **Connectivity Explorer** application). Alternatively, use the Live -> Add Row command form the main menu.

   In the **Live Point Data** sub-window (at the bottom), a new row will be displayed in the grid. The row contains information about the point selected, and dynamically changing value and timestamp(s), and other related information (e.g. diagnostics).
7. In the **Live Point Data** sub-window, click on the changing number under the Value column header. This should leave only this single cell selected (highlighted).
8. Using the mouse, drag the selected grid cell to the worksheet area of your Excel workbook, and drop it onto a cell of you choice. This will fill the cell with a special formula. The OPC value shows in the cell, and it updates itself dynamically.

   As an alternative to drag-and-drop, you can copy the grid cell from the **Live Point Data** sub-window using the Edit -> Copy command form the **Connectivity Explorer** menu, using the Copy button on the main toolbar, or with

the ***Ctrl+C*** keyboard shortcut. Then, paste the dynamic data to the Excel worksheet.

Where do I go from here?

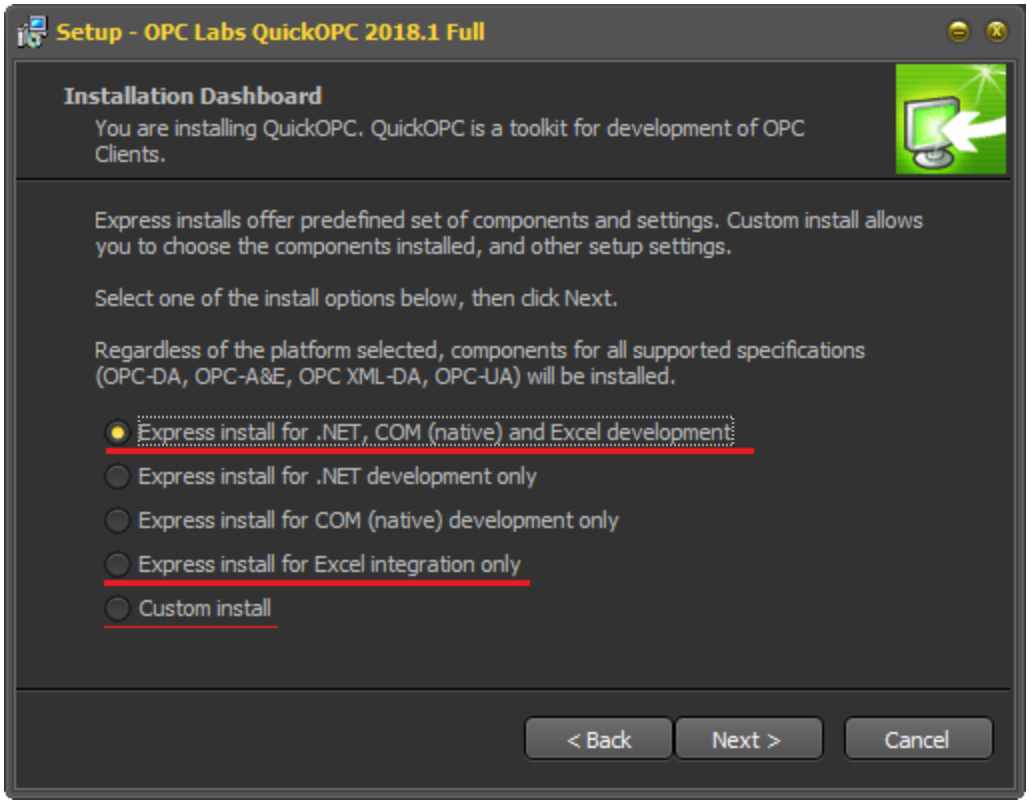
You now have a basic idea of how to use the OPC Data Client. There are many additional resources that you can use to gain additional knowledge about the product. Here are some of them:

- Play with the Demo application (accessible from the Start menu) and explore the various functionalities that the product provides.
- Read the User's Guide.
- Study the Reference documentation.
- Review the additional examples and tools included with the product.

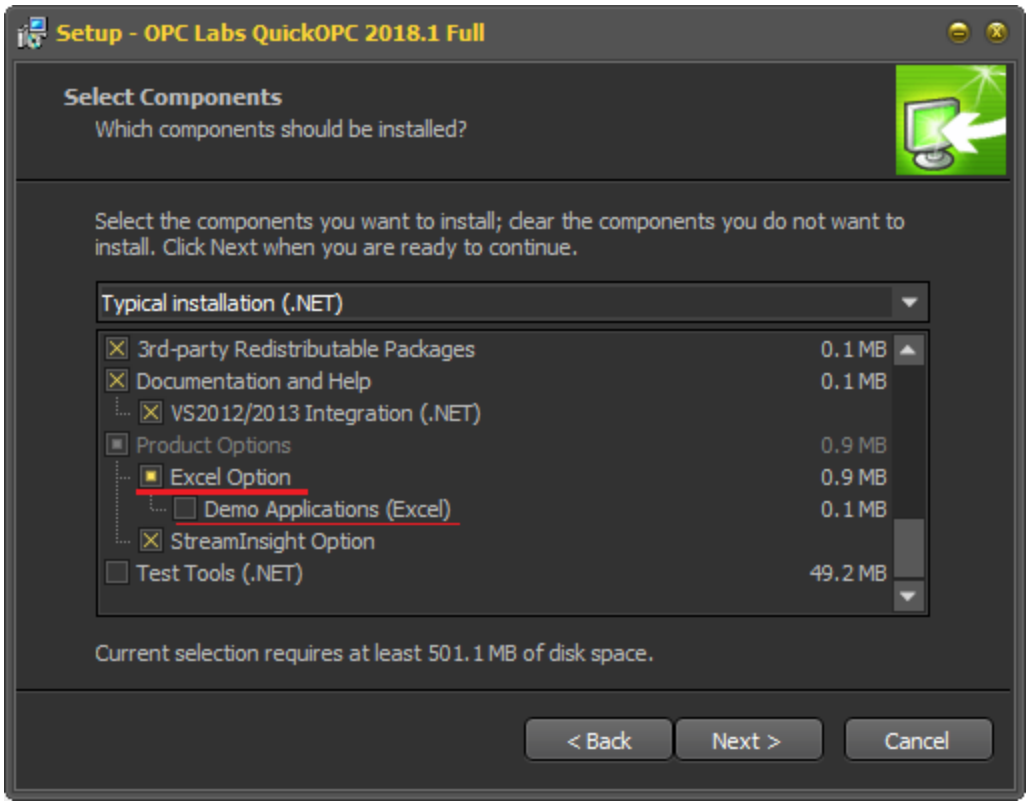
12.1.3 Excel Option - Installation

Excel Option is part of normal OPC Data Client standalone installer (full or production), but it needs to be properly enabled during installation. If you want to work with Excel Option, make sure you have selected the proper choice when installing the product. If you are not sure, run the installation again, making the choices as described below.

In order to have the Excel Option installed with OPC Data Client, select one of the red underlined options on the Installation Dahsboard page of the setup wizard:



If you opt to make a Custom Install, the Excel Option is then listed on the Select Components wizard page, and needs to be enabled there:



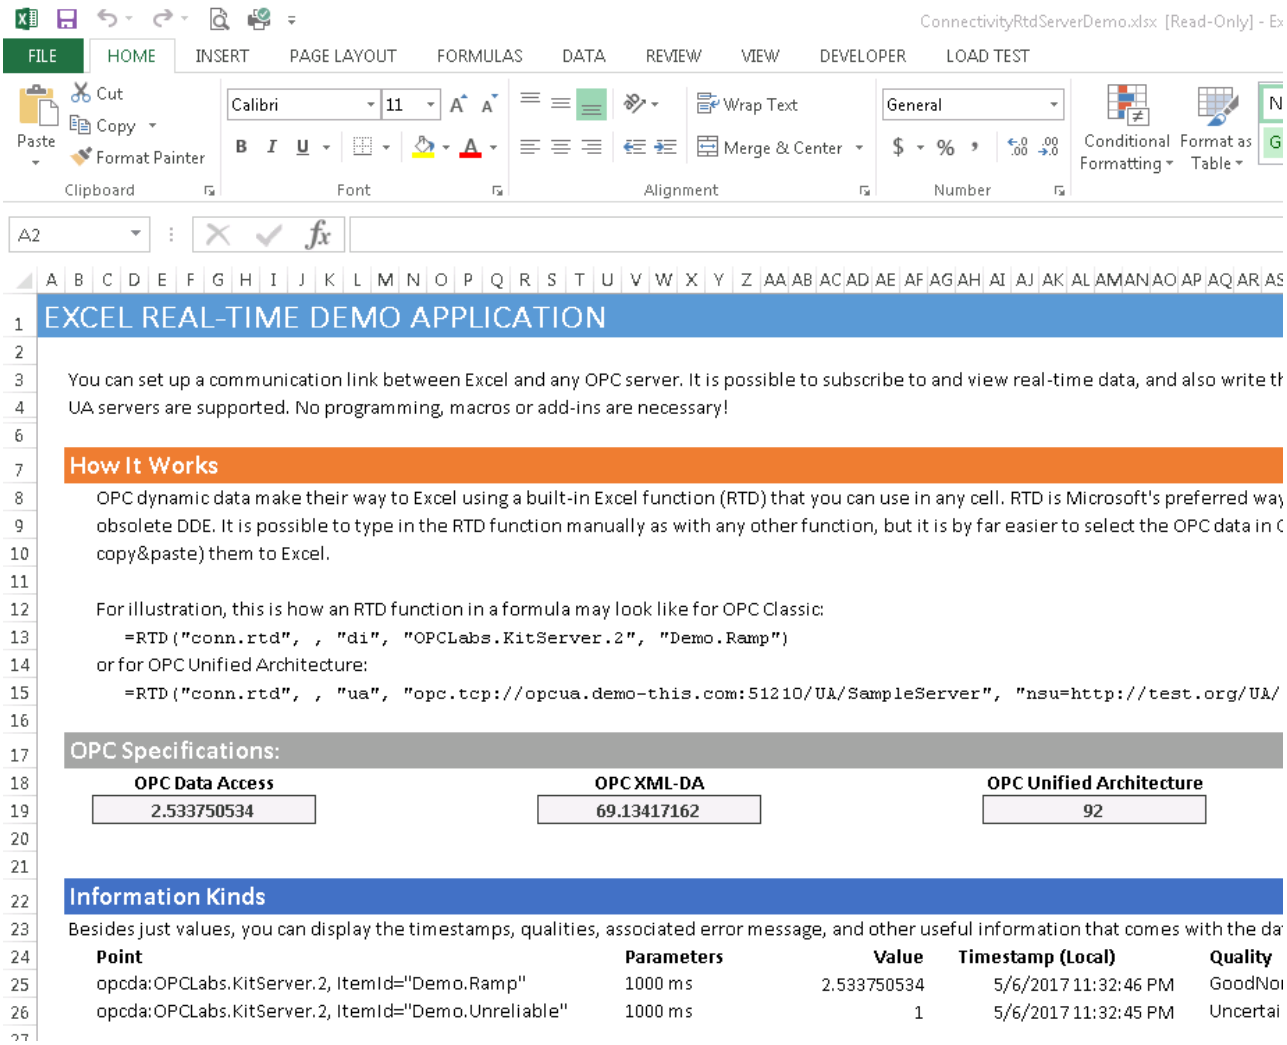
Excel Option is not contained in the OPC Data Client NuGet packages.

12.1.4 Excel Demo Applications

OPC Data Client installs with a demo workbook that shows the basic Excel integration features of the product (Excel Real Time Data). The demo workbook is available from the Start menu or the Launcher application. It shows:

- Principles of operation, and examples of RTD functions.
- OPC specifications that are supported, with live data coming in via each of the specifications.
- The kinds of information that can be accessed.
- Bidirectional communication (OPC writes).
- Examples of various data types supported.

For illustration, a part of the workbook is shown the following figure.



12.1.5 Excel Option Fundamentals

OPC dynamic data make their way to Excel using a built-in Excel function (RTD) that you can use in any cell. RTD is Microsoft's preferred way to get real-time data into Excel, instead of the obsolete DDE. It is possible to type in the RTD function manually as with any other function, but it is by far easier to select the OPC data in **Connectivity Explorer (Section 11.2)** tool, and drag-and-drop (or copy&paste) them to Excel. The RTD function addresses a so-called **Connectivity RTD Server (Section 12.1.5.1)**, a COM component that is part of the Excel Option, and this RTD server then performs the necessary communication with the data source.

In design-time, you would therefore typically use the **Connectivity Explorer (Section 11.2)** to locate the dynamic data and transfer them to the Excel worksheets you are creating, or you would type in the formulas containing the RTD functions directly into Excel.

In run-time, only the **Connectivity RTD Server (Section 12.1.5.1)** has to be installed on the computer, for your Excel worksheets to be functional.

12.1.5.1 Connectivity RTD Server Fundamentals

This article describes how the syntax of the Excel RTD function to be used with Excel Option. When used in the way described here, the RTD function retrieves real-time data using the Connectivity RTD Server.

In This Topic

RTD Function Syntax

Use the following syntax in Excel (the '=' designates a formula):

```
=RTD(RealTimeServerProgID, ServerName, Topic1, [Topic2], ...)
```

where the function arguments are as follows:

- *RealTimeServerProgID*
  A string that represents the Program ID of the Connectivity RTD server. *RealTimeServerProgID* is a required argument.
- *ServerName*
  A string that represents the name of the server on which the RTD server is to be run. If the RTD server is run locally, the *ServerName* should be an empty string ("") or omitted.
- *Topic1*, [*Topic2*], ...
  Strings that determine the data being retrieved. You can use from one to 28 topics, although only one topic is required.

RealTimeServerProgID Argument

For Connectivity RTD Server, use one of the following ProgIDs as the *RealTimeServerProgID*:

```
"opclabs.office.excel.connectivityrtdserver"
```

or

```
"conn.rtd"
```

Both these ProgIDs are equivalent. The second one is intentionally short, intended for manual typing into Excel.

> ProgIDs are case insensitive.

ServerName Argument

The Connectivity RTD Server is usually run locally (i.e. on the computer where Excel runs), and you should therefore omit the *ServerName* argument.

Topic Arguments

The topic arguments determine the data to be retrieved. See **Topic Syntax (Section 12.1.5.1.1)** for details.

Examples

For illustration, this is how an RTD function in a formula may look like for OPC Classic:

```
=RTD("conn.rtd", , "di", "OPCLabs.KitServer.2", "Demo.Ramp")
```

or for OPC Unified Architecture:

```
=RTD("conn.rtd", , "ua", "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=11218")
```

- RTD function
- How to set up and use the RTD function in Excel - Microsoft Support

12.1.5.1.1 Topic Syntax

As explained in **Connectivity RTD Server Fundamentals (Section 12.1.5.1)**, the RTD function syntax contains a number of topic arguments - at least one, but there can be more. The synatx and semantics of the topic arguments is given by the RTD server being used. The OPC Data Client Excel Option uses its internal Connectivity RTD Server, and the syntax of topic arguments is described here.

In This Topic

Topic Formats

The Connectivity RTD Server supports two formats of topics sequences in the RTD function.

The so-called friendly topic syntax is designed to be easily understandable by humans, and can also be manually typied in without too much effort. This format cannot, however, fully describe all possible requirements, due to the number of properties that can theoretically be set on different points and operation parameters.

For this reason, a second format, XML-based (XML Toipc Syntax) is also supported by the Connectivity RTD Server. This format can describe all requirements without loss, but is much less readable, and not really suitable for manual creation.

> By default, the Connectivity Explorer application creates RTD functions with topics formatted in the friendly topic syntax, whenever possible. The Connectivity Explorer automatically switches to the XML topic syntax if it detects that the given data cannot be described without loss in the friendly topic format.

Friendly Topic Syntax

With the friendly topic syntax, the overall sequence of topic arguments for Connectivity RTD Server is as follows:

```
typeString, pointIdentifier1, pointIdentifier2, ..., subscribeParameter1,
subscribeParameter2, ... [,
resultValueSelector]
```

Where:

- *typeString* denotes the type of point this RTD function is subscribing to. The type is given by an alias; it can be e.g. "opcdaitem", "opcdaproperty", or "opcuaattribute". See **Point Types Reference (Section 16.5)** for details on available point types and their type aliases. Type aliases are case insensitive.

- *pointIdentifier1*, *pointIdentifier2*, ... are topics that describe the point to be subscribed to. Their number, syntax and semantics depends on the type of the point. See **Point Types Reference (Section 16.5)** for details on point identifiers for each point type.
- *subscribeParameter1*, *subscribeParameter2*, ... are topics that describe the parameters of the Subscribe operation on the point. Their number, syntax and semantics depends on the type of the point. See **Point Types Reference (Section 16.5)** for details on point identifiers for each point type.
- *resultValueSelector* is a text string that determines the specific piece (or pieces) of information that will be extracted and displayed from a target object. For details, see **Result Value Selector (Section 11.2.2)**.

Further topics may be appended to the end of this sequence if the **Topic Write with RTD Server (Section 12.1.5.1.2)** feature is used.

XML Topic Syntax

The XML topic syntax is capable to fully describe the point and parameters. It is currently not documented, and is subject to change.

Topic Spanning

Some limitations of the RTD function make it problematic to pass the data to it. For example, each topic (string) must not be longer than 255 characters. This is normally not an issue with the friendly topic syntax, but can easily occur with XML topic syntax, where the resulting XML strings tend to be quite long. The Connectivity RTD Server (and the associated integrated functionality in Connectivity Explorer) overcome this limitation by spanning the topics strings over several RTD function arguments. The first topic contains information about how the arguments are laid out in the topic strings. The precise syntax and semantics of this topic spanning feature is currently not documented, and is subject to change.

Examples

Friendly topic syntax example for an OPC-DA item:

```
   "opcdataitem", "OPCLabs.KitServer.2", "Demo.Ramp"
```

Friendly topic syntax for OPC Unified Architecture:

```
   "opcuaattribute", "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer",
"nsu=http://test.org/UA/Data/;i=11218"
```

12.1.5.1.2 Topic Write with RTD Server

You can write values from Excel back to an OPC server too. This is usually done by appending a source cell reference to the list of RTD function arguments.

The RTD function in this mode works like normally, but in addition, it writes the value from the referenced cell into the data source (OPC server). The write occurs every time whenever the RTD function is evaluated (at the beginning, when explicitly invoked, or whenever its parameters change).

In This Topic

> ⚠ Use the **Topic Write** feature carefully.
>
> This feature is basically a "trick", it uses the RTD function of Excel for something it was not designed for. As such, it

has its risks and limitations.

One issue comes from the fact that the RTD function is evaluated anew (and therefore, a Write occurs) not only when the value to be written changes, but also initially - for example, when the worksheet with the RTD function is opened. If you use the Topic Write feature of the RTD server, your overall design must be such that this kind of behavior does not cause a problem.

Friendly Topic Syntax

In order to use the Topic Write feature, add the following sequence of topics to the end of the normal sequence, as described in **Topic Syntax (Section 12.1.5.1.1)**.

```
valueToWrite [, writeParameter1, writeParameter2, ... [, inputElementPath]]
```

Note that if there are optional arguments at the end of the original topic sequence, before the Topic Write arguments (for a particular point type and parameters, or for the result value selector), all such parameters must be given first (i.e. cannot be left out). In Excel, you can simply use commas to indicate their presence; the actual values (empty strings) are not necessary, though.

XML Topic Syntax

The XML topic syntax is capable to fully describe the write parameters. It is currently not documented, and is subject to change.

Examples

The following formula in Excel continuously displays values of the boiler level setpoint item. At the same time, any initial and new value from the cell A2 is written to the setpoint item.

```
=RTD("conn.rtd", , "da", "OPCLabs.KitServer.2", "Boilers.Boiler #1.LC1001.SetPoint", ,
"Value;""""", A2)
```

12.1.5.2 RTD Server Data Conversions

The usual conversions performed by OPC Data Client on the data take place. For details, see:

Data Types in OPC Classic (Section 9.9.1)

- **Data Types in OPC Classic (Section 9.9.1)**
- **Data Types in OPC-UA (Section 9.9.2)**

In This Topic

In addition, the Connectivity RTD Server makes following conversions before returning the data through the RTD function:

- Null values are converted to empty strings.
- Generic objects are converted to their string representations.
- 64-bit and wider integers and decimals are converted to strings (this avoids loss of precision).

Dates and Times

The dates and times are represented as floating point number in Excel internally, and are transferred as such to Excel from the Connectivity RTD Server. When dates or times from the Connectivoty RTD Server are displayed by Excel, by default the general number format is used. You need to set the cell format manually as needed. For example, you can use one of the pre-defined Date or Time formats that Excel offers, or a custom format, like (e.g.):

```
m/d/yyyy h:mm:ss AM/PM
```

You may also want to read: Format numbers as dates or times.

12.1.5.3 Connectivity Explorer Integration with Excel

The **Connectivity Explorer (Section 11.2)** application is designed to serve as a primary source of dynamic data items for use in Excel. As such, it contains several features that provide tight integration with the Excel Option.

In This Topic

Excel Clipboard Formats

Copy data as dynamic

When the **Copy data as dynamic** box in the **Options** dialog in **Connectivity Explorer** is checked, dynamic data transferred from the Connectivity Explorer through clipboard or drag-and-drop are transformed into RTD function calls, which allows them to remain dynamic when used in Excel.

When this box not checked, dynamic data transferred from the Connectivity Explorer simply contains their current value, static.

Use RTD friendly format

When the **Use RTD friendly format** box in the **Options** dialog in **Connectivity Explorer** is checked, and when the actual point and parameters used allow it, the generated RTD function calls use a friendly topic format, which is easier to read and modify by a human. The friendly format uses a short series of arguments as topic strings in the RTD function.

When this box is not checked (or when the actual point and parameters used cannot be expressed in the friendly format), the generated RTD function call will specify the topic strings using XML (more lengthy, and less readable).

Copy in Excel format

When the **Copy in Excel format** box in the **Options** dialog in **Connectivity Explorer** is checked, (static) data transferred from the Connectivity Explorer through clipboard or drag-and-drop are formatted with Excel in mind. This setting tries to bypass some Excel "intelligence" that causes incorrect data imports.

Some examples of what this settings is trying to do:

- Prevent Excel from interpreting strings that begin with plus or minus sign, a decimal point, or a digit, as numbers.
- Prevent Excel from interpreting strings that "look like" dates or times as being actual dates or times.
- Assure proper transfer of Boolean values.
- Assure that date and time values will be transferred without misinterpretation, independent of any language or regional settings.
- Assure that time values do not lose milliseconds or even seconds.

- Assure that date and time values will be formatted by Excel as such.

Uncheck this box if you need to transfer data to programs other than Excel.

Synchronized Connectivity Configuration

Configure RTD server connectivity

When the **Configure RTD server connectivity** box in the **Options** dialog in **Connectivity Explorer** checked, any changes you make to the connectivity cofiguration (see **Configure Connectivity Command (Section 11.2.3.2)**) are also saved for use by the Connectivity RTD Server. This assures that your Excel spreadsheets with the RTD functions will use the same connectivity configuration as the one in the Connectivity Explorer. Note that you may have to restart Excel in order for any setting changes to take effect.

12.1.6 Excel Option Application Deployment

This chapter describes how to deploy Excel solutions developed with use of OPC Data Client Excel Option.

For some uses, it is acceptable to perform the deployment manually. In other cases, you will find yourself writing an installer for your application, and you will probably want to include the installation of OPC Data Client components in it as well. A Production installer (part of OPC Data Client) can help with that.

> This chapter is only concerned with deploying RTD the server part of the Excel Option. That is sufficient for run-time. The Connectivity Explorer tool is used in design-time only, and therefore does not need to be deployed with the solution.

12.1.6.1 Excel Option Installation Elements

The elements described in this chapter need to be installed with your solution based on OPC Data Client Excel Option.

You need to deploy:

1. The Excel files (workbooks) that contain your solution, along with any associated files.
2. The Connectivity RTD Server.

12.1.6.1.1 Connectivity RTD Server Installation Elements

For Excel worksheets with RTD functions referring to Connectivity RTD Server, you need install following files:

- App_Web_OpcLabs.EasyOpcClassicRaw.amd64.dll
- App_Web_OpcLabs.EasyOpcClassicRaw.x86.dll
- OpcLabs.BaseLib.dll
- OpcLabs.BaseLibForms.dll
- OpcLabs.BaseLibPresentation.dll
- OpcLabs.EasyOpcClassic.dll
- OpcLabs.EasyOpcForms.dll

- OpcLabs.EasyOpcUA.dll
- **OpcLabs.OfficeConnector.dll**

You will find them under the **Bin** subdirectory in the installation directory of the product.

In addition, you need to register the **OpcLabs.OfficeConnector.dll** assembly using the Assembly Registration tool (**Regasm.exe**). The Assembly Registration tool is a part of .NET Framework, and is therefore available on every computer that has the .NET Framework installed.

For more information, please refer to http://msdn.microsoft.com/en-us/library/tzat5yw6(v=vs.110).aspx. It is recommended that you use the **/codebaseoption** when registering the assembly.

> ⚠ On 64-bit systems, a 32-bit and a 64-bit version of **RegAsm.exe** are present. Using the 32-bit version of **RegAsm.exe** registers the assembly for use by 32-bit Excel, and using the 64-bit of **RegAsm.exe** registers the assembly for use by 64-bit Excel. Depending on your Excel bitness, you need to select the proper version of **RegAsm.exe**.

12.1.6.2 Excel Option Configuration Elements

The elements described in this chapter need to be configured in your solution based on OPC Data Client Excel Option.

12.1.6.2.1 Connectivity RTD Server Configuration Elements

If you needed to change the connectivity configuration in order to develop your solution, you will also need to make sure that the same connectivity configuration is in effect for your users.

The connectivity configuration data for the Connectivity RTD Server is stored in the following file (optional):

- ***<CommonApplicationData>*\Connectivity RTD Server\ConnectivityConfiguration2.xml**

The ***<CommonApplicationData>*** folder is the directory that serves as a common repository for application-specific data that is used by all users. Its actual location depends on your system; it can be e.g. **C:\ProgramData**.

Most likely, you will not create this file manually. You will rather take the connectivity configuration file from the computer where you have developed your solution, and then place it onto user computers.

12.1.7 Excel Option Troubleshooting

If you do not get the expected value in Excel, you may be left without an error message that would guide towards the cause of the problem.

In order to see the related status and error messages, you can add cells that refer to this information. To do so, from Connectivity Explorer, drag-and-drop or copy-and-paste (in addition to the formula you already have) also the cells under "**Quality**" (OPC Classic), "**Status**" (OPC UA) and "**Error Message**" columns.

You can also create formulas that combine either the value, or the error message in the same cell, depending on a condition. Refer to **Topic Syntax (Section 12.1.5.1.1)** and **Result Value Selector (Section 11.2.2)** for more details.

12.1.8 Additional Resources for Excel Option

Study the Reference documentation (also available from Start menu).

Explore the demo installed with the product.

Check the vendor's Web page for updates, news, related products and other information.

RTD Object (Excel)

Security settings and Excel RealTimeData servers

12.2 StreamInsight Option

12.2.1 Introduction to StreamInsight Option

OPC Data Client is a toolkit for writing OPC client applications. Microsoft StreamInsight is a platform for writing and running complex event processing (CEP) applications.

The StreamInsight Option for OPC Data Client allows you to bring in data from OPC sources into StreamInsight, analyze them and process them further, and even feed the results back to OPC servers. Data from OPC can be combined with data from multiple other sources. You can monitor the data for meaningful patterns, trends and exceptions. Data can be analyzed and correlated while they are in-flight.

The StreamInsight Option for OPC Data Client supports connections to OPC servers with following specifications:

- OPC Data Access
- OPC Alarms and Events
- OPC Unified Architecture (data access)

> This functionality is not yet available for OPC UA PubSub.

The StreamInsight support in OPC Data Client is not separate from its other parts. Instead, it builds on top of many features and components already available in OPC Data Client. Specifically, the StreamInsight Option makes ideal usage of the connection-less approach in OPC Data Client, and the reactive programming model (OPC Reactive Extensions, Rx/OPC). This means that you can also easily combine the StreamInsight development with all other options and features provided by OPC Data Client.

This part of the documentation provides information that is specific to the StreamInsight Option for OPC Data Client. You should be able to follow the main ideas presented here without advance knowledge of OPC Data Client, but for serious development, you will need OPC Data Client knowledge as well. For information about OPC Data Client itself, please refer to corresponding OPC Data Client documentation parts, such as the Users' Guide, or the Reference documentation.

> For in-memory streaming analytics, check out also Microsoft Trill (https://github.com/microsoft/Trill). OPC Data Client can interoperate with Trill seamlessly. See **Installed Examples - Console - SimpleTrillApplication (Section 13.1.4.1.9)**.

> The features discussed here, or some of them, may not be available in all editions of the product. Check the Product Editions page for differences between the editions. The trial license has all features enabled (and is limited in period for which it provides valid data), but licenses for specific commercial editions may have functionality limitations.

12.2.2 StreamInsight Option Installation and Getting Started

The StreamInsight Option for OPC Data Client is installed together with the OPC Data Client product, as described further below (there is no separate installation package). Please refer to the Installation section of this document if you need details about the OPC Data Client installation procedure.

12.2.2.1 StreamInsight Option Licensing

The StreamInsight Option for OPC Data Client is a licensed product. You must obtain an appropriate license to use it in development or production environment. For evaluation purposes, you are granted a trial license, which is in effect if no

other license is available.

With the trial license, the components only provide valid OPC data for 30 minutes since the application was started. After this period elapses, performing OPC operations will return an error. Restarting the application gives you additional 30 minutes, and so on. If you need to evaluate the product but the default trial license is not sufficient for you purposes, please contact the vendor or producer, describe your needs, and a special trial license may be provided to you.

12.2.2.2 Installing a StreamInsight Instance

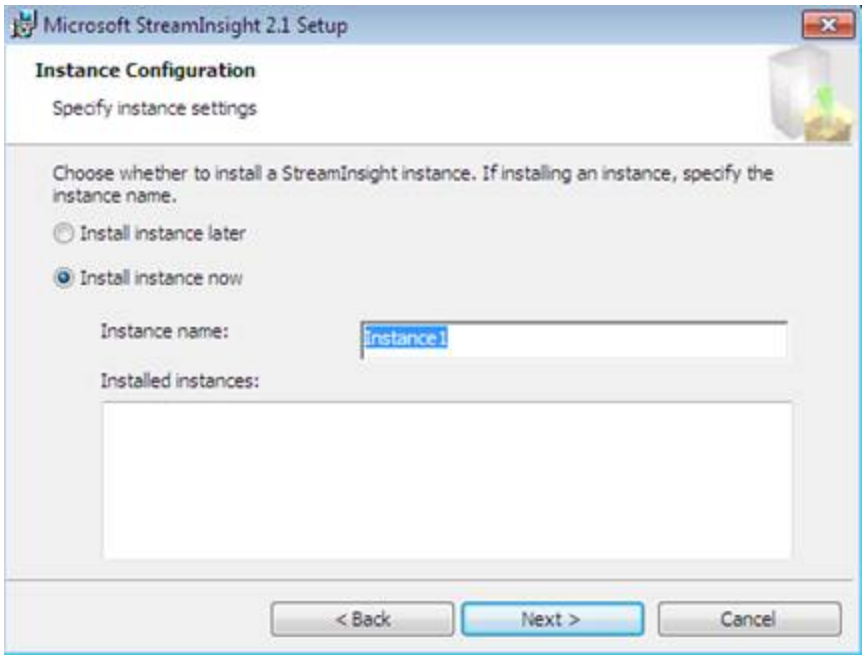
The Getting Started procedures assume an existence of a local StreamInsight instance named Instance1. You need to install Microsoft StreamInsight 2.3, and create this instance. General setup instructions to Microsoft StreamInsight can be found here: http://technet.microsoft.com/en-us/library/ee378749.aspx.

We have created our own summary of the steps needed, which you may find useful, and easier to follow:

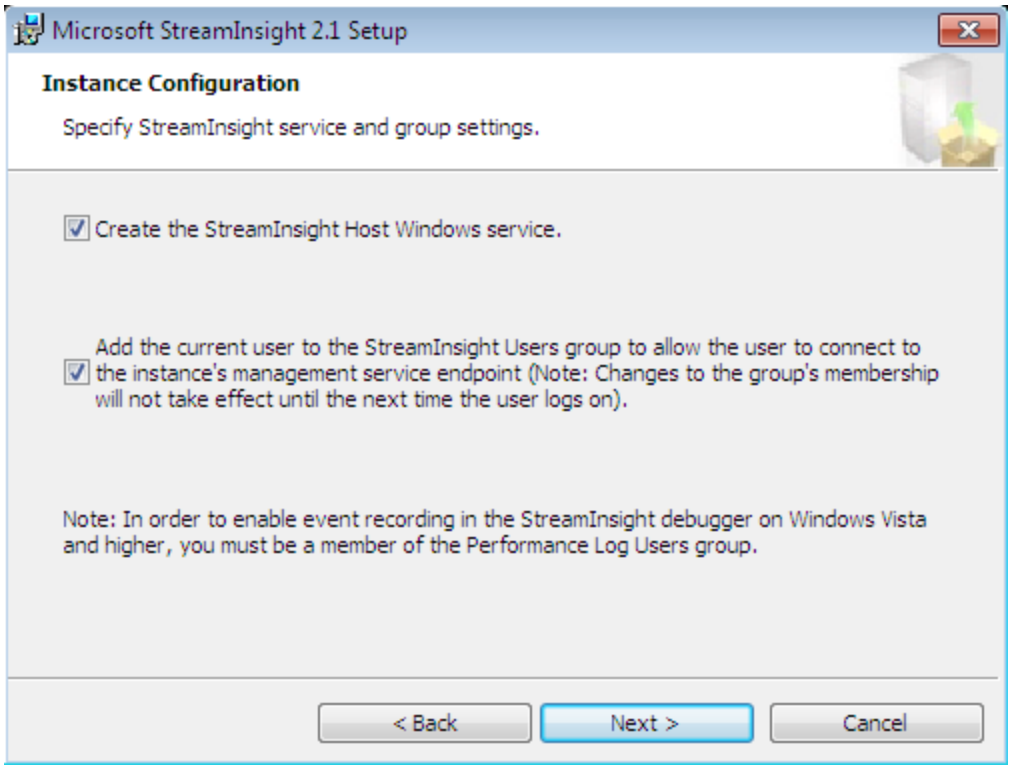
1. Download the x86 (for 32-bit operating systems) or x64 (for 64-bit operating systems) version of StreamInsight.msi (not StreamInsightClient.msi) from Microsoft (https://www.microsoft.com/en-us/download/details.aspx?id=42295, or search for "Microsoft SQL Server 2014 feature Pack"), and run it.

Note: Do not use StreamInsight installation from Microsoft SQL Server 2012 or earlier – it contains Microsoft StreamInsight 2.0 or older, which is not supported by StreamInsight Option for OPC Data Client. Also, StreamInsight 2.1 is not officially supported with this version of OPC Data Client.

2. Go through the installation wizard pages, accepting defaults or entering information as needed. On the "Instance Configuration" page, select "Install instance now" option, and enter "Instance1" (without the double-quotes) into the "Instance name" field. Creation of this instance is recommended now (although you can create it later), because it is the instance that we use in our examples.



3. Continue going through the installation wizard pages. We recommend that you check the "Add the current user to the StreamInsight Users group..." box. Finalize the installation wizard then.



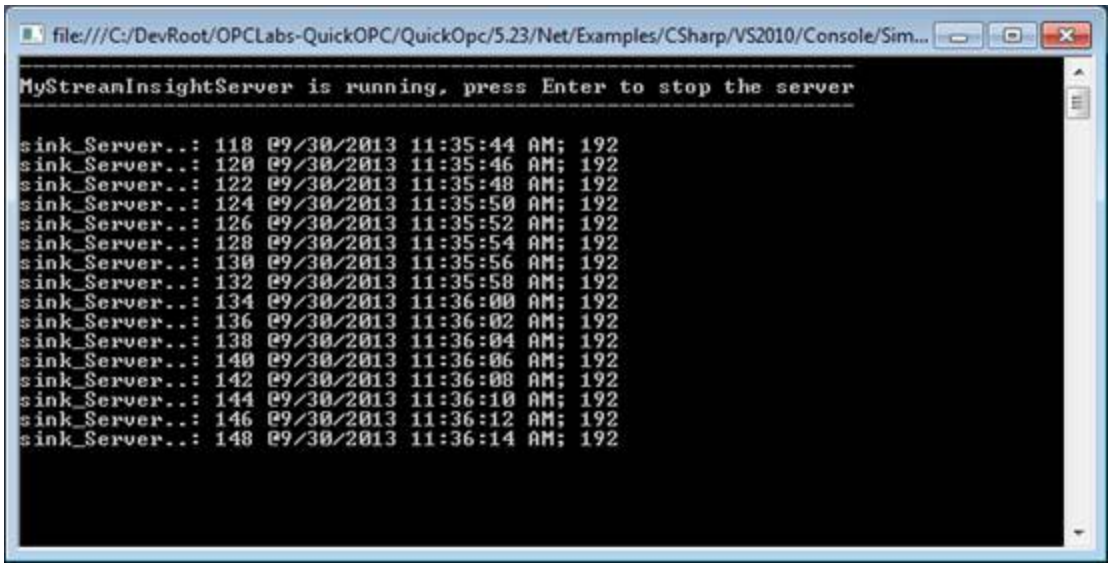
4. If you have checked the "Add the current user to the StreamInsight Users group..." box as instructed above, log out of Windows, and then log in again.

12.2.2.3 Building and Running a First StreamInsight Application with OPC

In this Getting Started procedure, we will build and run a console application in C# or Visual Basic that shows how to create an OPC Data Access event source, and query it for events carrying even data value.

We assume that you have already installed a StreamInsight instance named "Instance1", as described in the previous chapter. We also assume that you have Microsoft Visual Studio 2017 or later installed.

1. Install OPC Data Client. If you are reading this text, chances are that you have already done it. The "StreamInsight Option" installation component must be checked during the installation, but it is on by default, so unless you are doing a custom installation and choosing a non-default different installation type, you do not have to do anything special during the OPC Data Client installation.
2. From the Start menu (locate the OPC Data Client product submenu) or the Launcher application, and select "StreamInsight Option -> Examples Solution (Source Code)". This will open the solution in Visual Studio.
3. In the Solution Explorer of Visual Studio, double-click "Program.cs" under "SimpleDAStreamInsightApplication" project. This will give you a chance to review the one-page program we are going to build and run.
4. Right-click on "SimpleDAStreamInsightApplication" project in the Solution Explorer, and select "Debug -> Start new instance". This will build and run the program.
5. Observe the results in the console window, and after you receive enough events, press Enter to stop the server. The output should look similar to this:



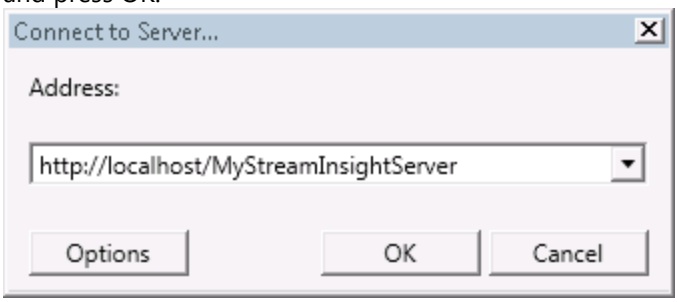
You can also try similar projects for other OPC Specifications:

- **SimpleAEStreamInsightApplication**: For OPC Alarms&Events (OPC-A&E), or
- **SimpleUAStreamInsightApplication**: For OPC Unified Architecture (OPC-UA).

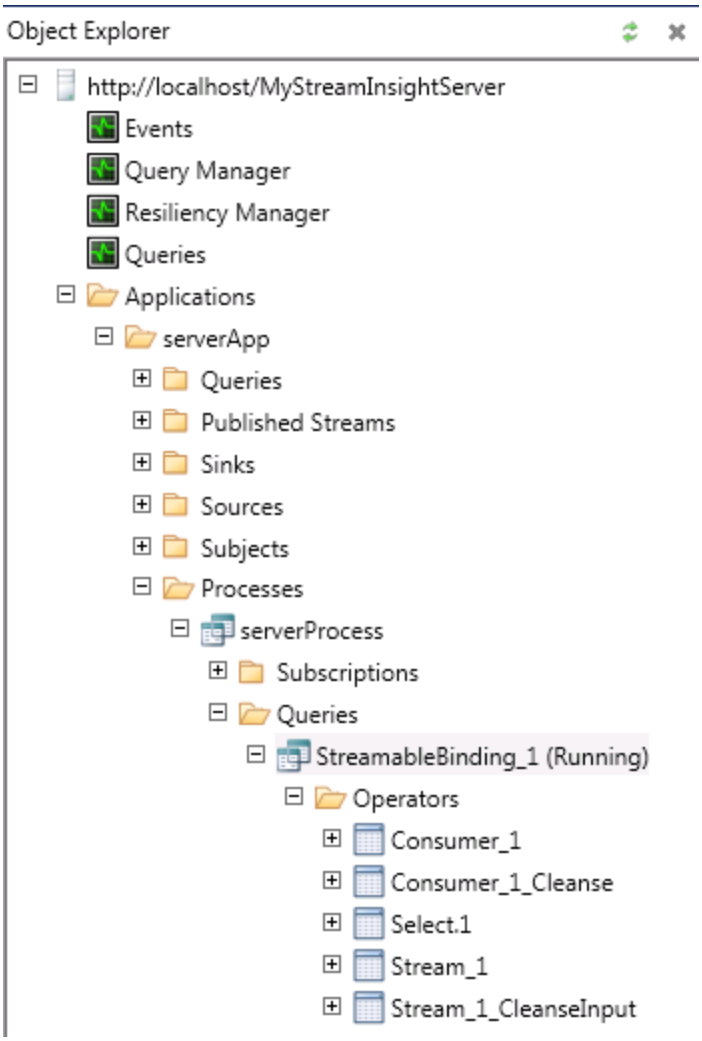
12.2.2.4 Debugging the StreamInsight Event Flow

In this Getting Started procedure, we will use the StreamInsight Event Flow Debugger to view how the events are internally processed in StreamInsight. We assume that you have performed the preceding Getting Started procedures already.

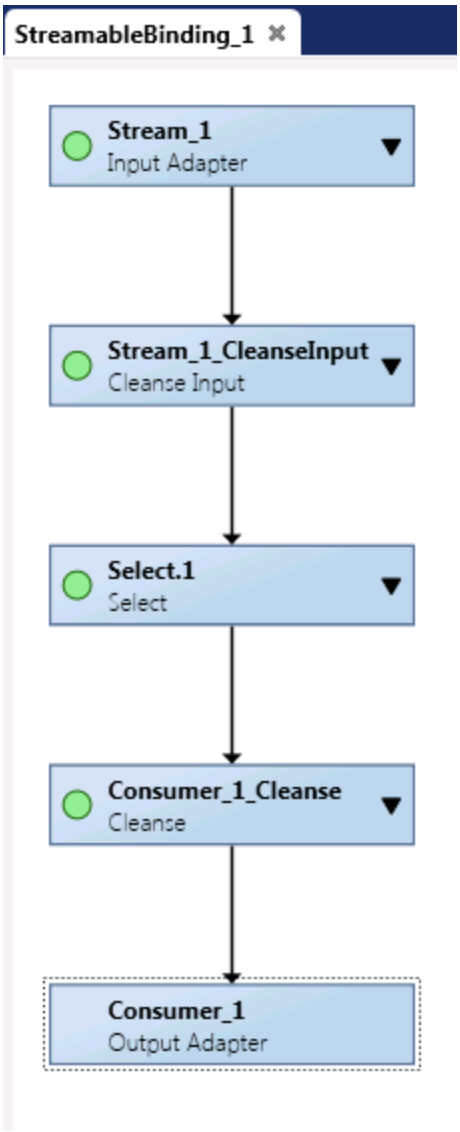
1. As before, right-click on "SimpleDAStreamInsightApplication" project in the Solution Explorer, and select "Debug -> Start new instance". This will build and run the program. Observe the results in the console window, but let the application run.
2. From the Start menu, select "Microsoft StreamInsight 2.3 -> StreamInsight Event Flow Debugger".
3. From the debugger menu, select "File -> Connect to Server... (Ctrl+K)" command.
4. In the "Connect to Server..." dialog, enter the address as http://localhost/StreamInsight/MyStreamInsightServer , and press OK.



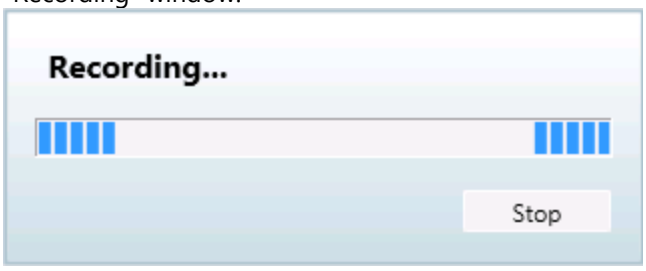
5. In the Object Explorer pane of the StreamInsight Event Flow Debugger, navigate and expand nodes as follows:



6. Under “Applications -> serverApp -> Processes -> ServerProcess -> Queries”, right-click the StreamableBinding_1 query node, and select the “Display Query” command. This will display the query flow chart:



7. Press the “Start Recording Events” button on the toolbar. If it happens to be disabled (grayed out), select the “Display Query” command again, as in the previous step. 
8. Let the events be recorded for some time (e.g. about a minute), and then press the “Stop” button on the “Recording” window:



Alternatively, you can press the “Stop Recording Events” button on the toolbar. 
9. You can now view the events at various stages of the query processing, by clicking the downwards-pointing triangle in any of the query operators. For example, events on the “Select.1” operator may look like this:

You can sort and/or filter the events according to various criteria, and the debugger also gives you analysis options, such as Root Cause Analysis or Event Propagation Analysis.

10. Close the StreamInsight Event Flow Debugger.
11. Switch to the console output window of the application, and press Enter to stop it and close the window.

12.2.3 StreamInsight Option Fundamentals

This chapter describes the fundamental concepts used within the StreamInsight Option for OPC Data Client.

12.2.3.1 StreamInsight Option Product Parts

12.2.3.1.1 StreamInsight Option Assemblies

The StreamInsight Option for OPC Data Client uses the core OPC Data Client assemblies described in the “OPC Data Client User's Guide”.

In addition, following assemblies are needed to develop programs with the StreamInsight Option for OPC Data Client:

Assembly Name or File	Title	Description
OpcLabs.OpcComplexEventProcessing	OPC Labs OPC Complex Event Processing	StreamInsight support for OPC-DA, OPC-A&E and OPC-UA (Unified Architecture) specifications

The assemblies are written to target Microsoft .NET Framework 4.5.

As with the core OPC Data Client Assemblies, the StreamInsight Option for OPC Data Client assemblies are also delivered with XML comment files and ReSharper annotations.

12.2.3.1.2 StreamInsight Option Examples

Example code, projects and solutions are available from the Start menu or the Launcher application. You can also access them from the file system, in the Examples-NET subfolder of the installation folder.

A separate Examples chapter in the StreamInsight Option documentation contain list of all examples and their purpose.

12.2.3.1.3 StreamInsight Option Documentation and Help

The StreamInsight Option documentation is part of the OPC Data Client User's Guide and Reference. You can also access it from the Start menu or the Launcher application.

In addition, there is IntelliSense and Object Browser information available from Visual Studio environment.

The help contents integrates Microsoft Visual Studio Help (Microsoft Help Viewer 2 format).

12.2.3.2 StreamInsight Option Usage

The StreamInsight Option for OPC Data Client is suitable for use from within wide range of tools or languages based on Microsoft .NET Framework. Most commonly, you will use from inside C# or Visual Basic project in Visual Studio.

The project can be e.g. a class library, a console application, Windows Forms or WPF application, or a Web service.

12.2.3.2.1 How the StreamInsight Option Works

The main purpose of StreamInsight Option for OPC Data Client is to make it easy to create StreamInsight event sources that generate data that come from underlying OPC servers. These event sources generate StreamInsight events that are then processed inside StreamInsight like any other events.

In order to bring OPC data to StreamInsight, you first reference the necessary OPC Data Client assemblies in your project. Then, in your code, you create instances of OPC “observables” – the reactive objects that call a specified method whenever new data is available. Several types of “observables” are available, for OPC Data Access, OPC Alarms and Events, and OPC Unified Architecture, respectively. The observables are then used to create event sources inside StreamInsight, by converting them to temporal streams.

12.2.3.2.2 Referencing the Assemblies

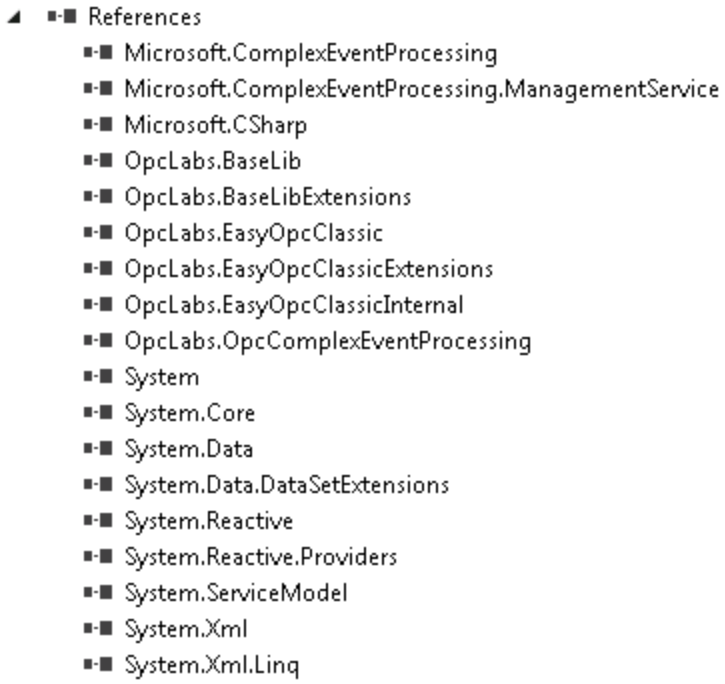
In order to develop applications with StreamInsight Option for OPC Data Client, your project first needs to reference the appropriate assemblies.

Besides the “standard” assemblies used in your project, and the assemblies you already have referenced for various specific purposes of yours, you will to reference:

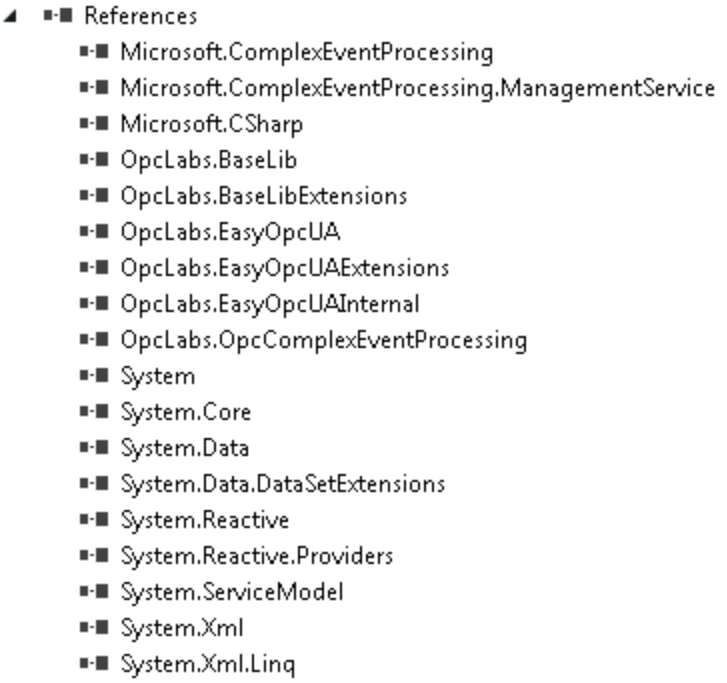
- The OPC Data Client assemblies needed for various tasks. They are described in the Product Parts section of the “OPC Data Client User's Guide” document.
- The StreamInsight Option for OPC Data Client assembly or assemblies (as listed in “Product Parts”) in this document
- Microsoft Reactive Extensions Assemblies (installed with Microsoft StreamInsight).
- Supporting Microsoft StreamInsight assemblies.

To make this a bit simpler, we have put together some illustrations below that summarize the assemblies that are typically referenced in your projects.

In a StreamInsight project that uses OPC “Classic”, the references list should look similarly to this:



In a StreamInsight project that uses OPC Unified Architecture, the references list should look similarly to this:



Note: In OPC Data Client version 5.40 and later, ignore the EasyOpcClassicExtensions, EasyOpcUAInternal and EasyOpcUAExtensions assemblies above – they are no longer needed, and no longer present.

You can also combine the two lists together, if you application needs both OPC "Classic" and OPC Unified Architecture servers.

12.2.3.2.3 Example Walkthrough

In this chapter, we will explain the usage of StreamInsight Option for OPC Data Client on one of the examples that comes with the product. It is the SimpleDAStreamInsightApplication project in C#. This example uses OPC Data Access; other examples, for OPC Alarms and Events, or OPC Unified Architecture, are quite similar.

In order to make it easy to understand the specifics of StreamInsight Option for OPC Data Client, and stay away from parts that common to all StreamInsight application, we have created this set of simple examples by deriving from the examples that Microsoft uses to teach StreamInsight. We can thus stay away from explaining the information that is already available by Microsoft.

Our example will expose an embedded server from inside a console application, and also run the query and display the results. It is based on Microsoft's "StreamInsight Example: Server - Exposing an Embedded Server", http://msdn.microsoft.com/en-us/library/hh995352(v=sql.111).aspx . It is recommended that you study the Microsoft's example first.

In This Topic

Introductory Steps

The first steps are the same:

- Create the (StreamInsight) server instance
- Create the (StreamInsight) application

Define and Deploy a Source

In the next step, an input source is defined and deployed to the (StreamInsight) server with a name so that it can be used by other StreamInsight clients. In this example, the data is a simple temporal stream of point events generated by the OPC Data Access server.

The DAItemChangedObservable.Create<int> method creates an observable that generates a sequence of EasyDAItemChangedEventArgs<int> objects. Each notification contains, among other information, the value of a given integer OPC item (if available), as it is delivered by the OPC server. Because the EasyDAItemChangedEventArgs<int> objects are not directly suitable as StreamInsight event payloads, we convert them to DAItemChangedPayload<int>, which is pre-made payload object provided by the StreamInsight Option for OPC Data Client.

Define and Deploy a Source

```
// DEFINE a simple SOURCE (returns a point event every second)
const string machineName = "";
const string serverClass = "OPCLabs.KitServer.2";
const string itemId = "Simulation.Incrementing (1 s)";
var observable = DAItemChangedObservable.Create<int>(machineName,
    serverClass, itemId, 100);
var mySource = myApp
    .DefineObservable(() => observable)
    .ToPointStreamable(
```

```
            eventArgs =>
                PointEvent.CreateInsert(DateTimeOffset.Now,
                (DAItemChangedPayload<int>)eventArgs),
            AdvanceTimeSettings.StrictlyIncreasingStartTime);
```

Compose a Query over the Source

Next, compose a query over the input source. The query uses LINQ as the query specification language. In this example, the query returns the events where the value of the OPC item is an even number.

Compose a Query over the Source

```
    // Compose a QUERY over the source
    // (return every event carrying even data value)
    var myQuery = from e in mySource
                  where e.VtqPayload.Value % 2 == 0
                  select e;
```

Technically, this definition translates to a filter operator that drops all events from the sequence that do not fulfill the filter predicate (where e.VtqPayload.Value % 2 == 0) and returns the event value. For more information about LINQ query operators, see Using StreamInsight LINQ.

Define and Deploy a Sink

Next, an output sink is created that can be bound to the query and process the resulting sequence. In this example, a simple function is created that simply writes the stream values to the console. The DAItemChangedPayload<int> class has a convenient ToString() method that returns the relevant payload information nicely formatted for output.

Define and Deploy a Sink

```
    // DEFINE a simple observer SINK (writes the value to the server console)
    var mySink = myApp.DefineObserver(() =>
        Observer.Create<DAItemChangedPayload<int>>(
            payload => Console.WriteLine("sink_Server..: {0}", payload)));
```

The sink is then deployed to the server with a name, in the same way as in the original Microsoft example.

Bind and Run the Query and Sink

The remainder of the example is not doing anything specific to OPC. The observable query is bound to the observer output sink, and the query is then run in a process in the server. This process continues to run until the user stops it by typing in the console.

12.2.3.3 Creating OPC Event Sources

The power of StreamInsight Option for OPC Data Client comes from its OPC event sources. On the surface, they are just

handful of relatively “small” objects, with uncomplicated interface. Below the surface, however, there is an enormous amount of functionality, providing things such as type conversions, error handling, connection pooling, connection persistence, optimizations, OPC compliance, wide interoperability, and security.

12.2.3.3.1 OPC Observables

The StreamInsight Option for OPC Data Client provides OPC event sources in form of OPC observables, i.e. .NET reactive object with IObservable interface. In order to simplify creation of these OPC event sources, static classes with various overloads of Create method are provided:

- In order to create OPC Data Access event source, call one of the DAItemChangedObservable.Create<TValue> method overloads, passing it arguments such as the OPC server ProgID, OPC item ID, and requested update rate.
- In order to create OPC Alarms and Events event source, call one of the AENotificationObservable.Create method overloads, passing it arguments such as the OPC server ProgID, notification rate, and subscription filter.
- In order to create OPC Unified Architecture (data) event source, call one of the UADataChangeNotificationObservable.Create<TValue> method overloads, passing it arguments such as the OPC server endpoint, OPC node ID, and sampling interval.

For more information and details on the OPC Observables, see the appropriate chapters (separately for OPC-DA, OPC-A&E, and OPC-UA) in the Reactive Programming Model section of this document.

12.2.3.3.2 Errors in OPC Sequences

When there is an error in communication with the target OPC server, the OPC observable sends a message (one of the XXXXEventArgs objects) with following characteristics:

- The Exception property is non-null, and contains an exception object that describes the error.
- The ErrorId property optionally contains a string that identifies the error.
- The ErrorMessage property contains a string that describes the error.
- The Succeeded property is equal to ‘false’.
- Other properties that normally contain the actual notification data may not contain valid data, or may be null.

Your StreamInsight application code needs to be prepared for such messages. As a minimum, if you want to ignore error situations, you need to filter out the error messages, and in case of error, do not access the fields of the XXXXEventArgs that do not contain valid data.

When you use the pre-defined OPC Event Payload classes (described further below), the conversion code already takes the possible errors into account, and behaves accordingly, by filling in the payload fields with default values, setting negative error code in the payload, etc.

Note that the errors described here are NOT errors in the sense of calling the OnError method of the IObserver interface. In fact, the OPC observables never call OnError, because that would mean an irrecoverable error and a completion of the sequence. The OPC errors are, however, potentially transient and recoverable, and must therefore be a part of normal notifications.

12.2.3.3.3 Other Special Cases in OPC Sequences

Leaving error situations aside, you still need to be careful when interpreting properties of XXXXEventArgs objects provided by the OPC observables. For precise description, study the corresponding topics int the “OPC Data Client User's Guide”

and the reference documentations. Here are some basic points to be aware of:

- In OPC Data Access, the EasyDAItemChangedEventArgs<T>.TypedVtq.TypedValue property does not contain valid data when the quality of the VTQ denotes a "Bad" quality.
- In OPC Alarms and Events, the EasyAENotificationEventArgs.EventData property does not contain valid data for in a notification that signifies a re-gained connection to the OPC server, or in a notification that indicates that a subscription refresh is complete.
- In OPC Unified Architecture, the EasyUADataChangeNotificationEventArgs<T>.TypedAttributeData.TypedValue property does not contain valid data when the status code of the attribute data denotes a "Bad" status.

When you use the pre-defined OPC Event Payload classes (described further below), the conversion code already takes these special cases into account, e.g. by filling in the payload fields with special values.

12.2.3.4 OPC Event Payloads

When you develop application for Microsoft StreamInsight, you are responsible for defining *event payloads*, i.e. .NET data structures that hold the data associated with StreamInsight events. The fields in the payload are user-defined and their types are based on the .NET type system.

There are various rules and limitations regarding the design of event payloads for Microsoft StreamInsight. For details, refer to StreamInsight documentation, e.g. the "Event Structure" article (http://msdn.microsoft.com/en-us/library/ee378905(v=sql.111).aspx).

The objects provided as notifications by OPC observables are not directly suitable as StreamInsight event payloads. You need to define the event payload structure for StreamInsight according to the needs of your application. There is no general rule as to what to use as StreamInsight event payload – it all depends on the specifics of the application. You can, for example

- Pick up a single field from the notification provided by the OPC observable – for example, the actual data value. This may be very useful in applications that only need the data values, but beware of special cases such as communication errors etc.
- Create a custom .NET data structure, and define its fields and organize the data in it precisely as your application requires. Then, convert the notifications provided by the OPC observable, to instances of this >NET event payload structure.
- Use ready-made OPC Event Payload classes provided by the StreamInsight Option for OPC Data Client. These classes are already designed to conform to StreamInsight rules, and payload instances can be easily created by converting them from the notifications coming from OPC observables.

The following paragraphs describe the OPC Event Payload classes for various OPC specifications.

12.2.3.4.1 Common Payload Characteristics

All OPC Event Payload classes contain a string ErrorId field. This field is empty for successes, and non-empty for errors.

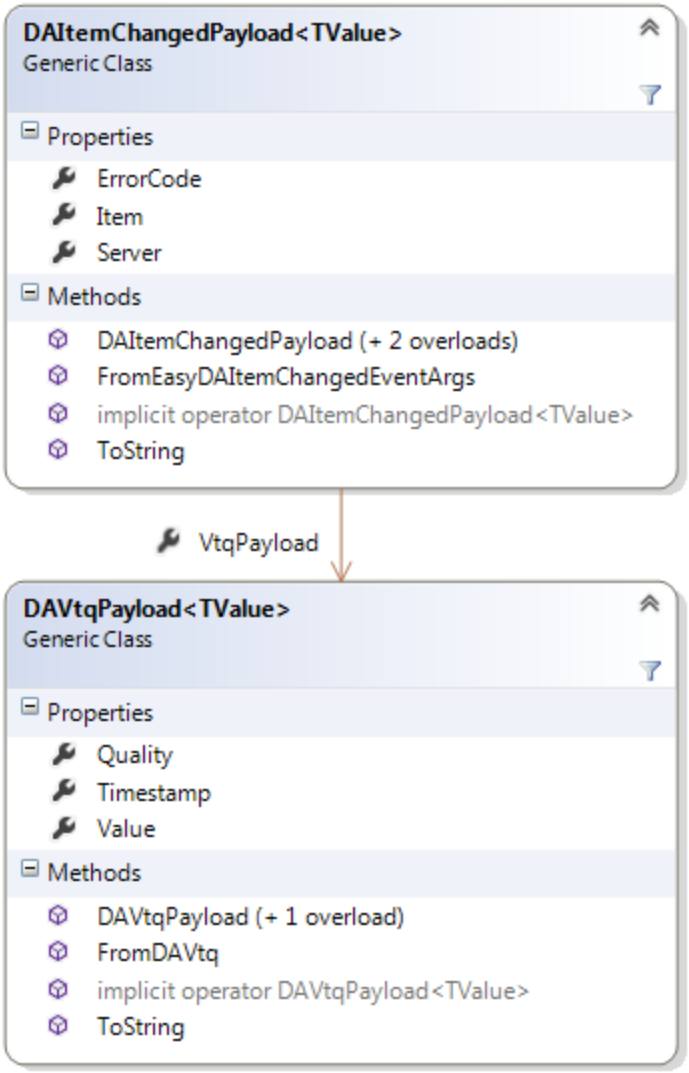
The OPC Event Payload classes contain no more information about the error (such as the error message), due to possible negative effect on the payload size, memory consumption, and performance. If your application needs extra information such as the error message strings, derive your payload from one of the OPC Event Payload classes and extend it, or use your own even payload structure.

Each OPC Event Payload class contains a method (called FromXXXX) that creates it from a non-payload object that comes natively from the OPC observable, and a corresponding implicit conversion operator.

For easy viewing, logging and similar purposes, all OPC Event Payload classes contain a ToString() method that formats the contents of relevant fields of the payload into a readable string.

12.2.3.4.2 Payloads for OPC Data Access

The event payload class for OPC Data Access is the DAItemChangedPayload<TValue>, where TValue is the type of the OPC values. This class contains an embedded DAVtqPayload<TValue> object, which contains the actual OPC value, timestamp, and quality. This object is always present; in case of errors, it contains default values.



In addition, there are Server and Item string properties, identifying the source of the event. For a single OPC observable, they always contain the same value, but they become useful once you start combining events from different OPC sources into one stream.

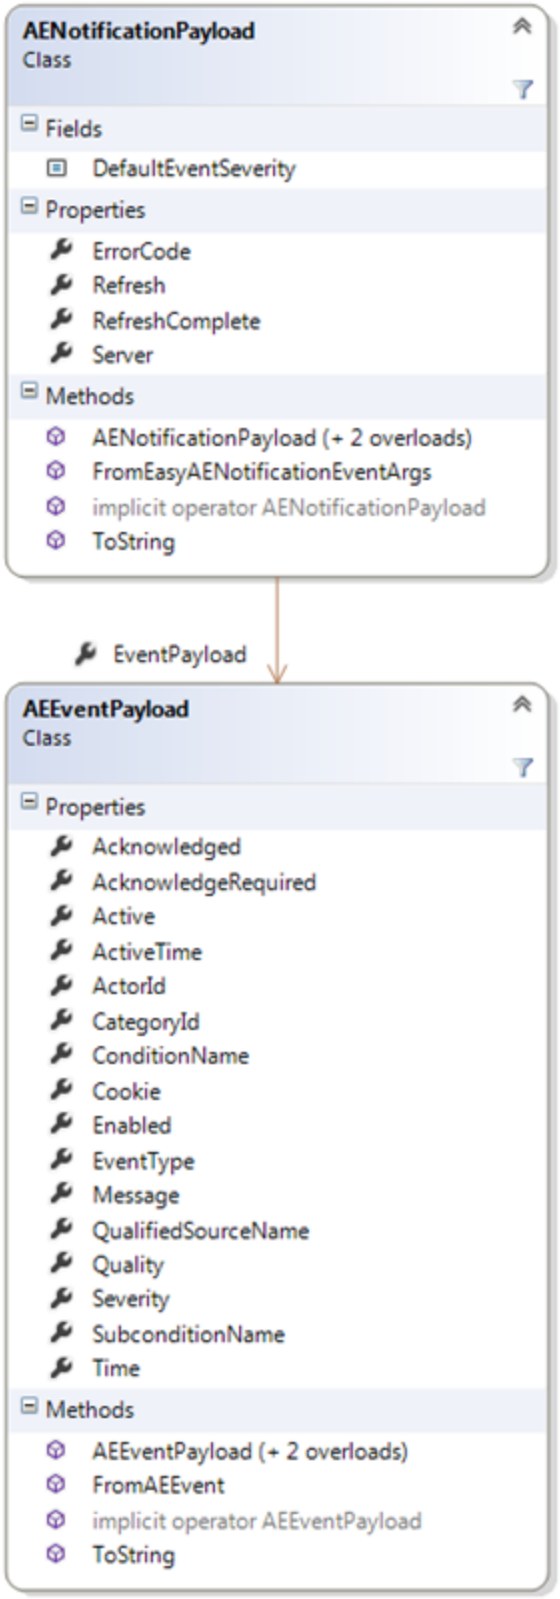
12.2.3.4.3 Payloads for OPC Alarms and Events

The event payload class for OPC Alarms&Events is the AENotificationPayload class. This class contains an

embedded AEEventDataPayload object, which contains the actual OPC event. This object is always present; in case of errors and special cases, it contains default or pre-defined values.

A special event priority value is used when no OPC event is present (in case of errors, but also re-gained connections, and a completed refresh). Normal OPC event priorities are in the range from 0(1) to 1000. When creating a payload for a notification where no actual OPC event is present, an event priority value of 9999 is used. The value 9999 is chosen to be higher than the severity of any OPC-A&E event, yet still in a 4-digit range.

The payload class does not contain any fields for OPC server-specific event attributes. If you need to process the OPC event attributes in StreamInsight, derive your own class from AEEventDataPayload, add the fields you need, and develop a code that extracts the attributes from the AEEventData object (in EasyAENotificationEventArgs.EventData).

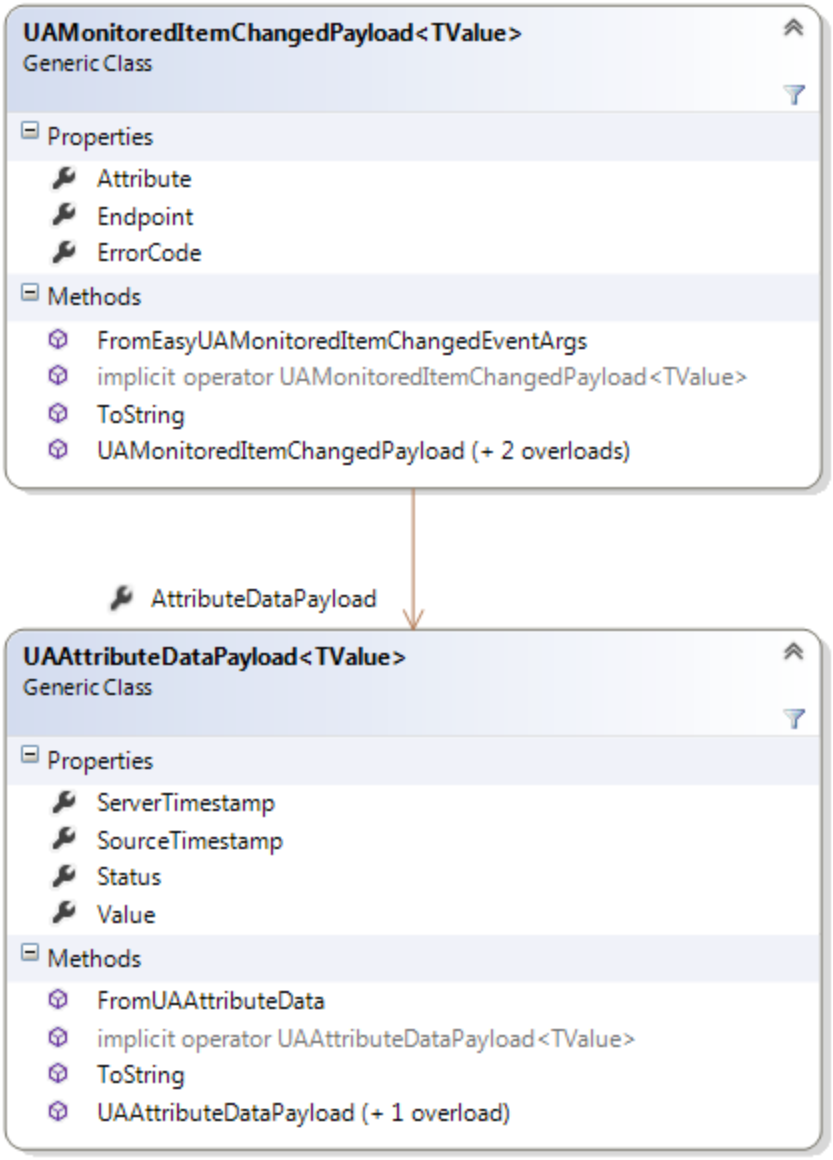


In addition, there is a Server string property, identifying the source of the event. For a single OPC observable, it always contains the same value, but it becomes useful once you start combining events from different OPC sources into one

stream.

12.2.3.4.4 Payloads for OPC Unified Architecture

The event payload class for OPC Unified Architecture is the UADataChangeNotificationPayload<TValue>, where TValue is the type of the OPC values. This class contains an embedded UAAttributeDataPayload<TValue> object, which contains the actual OPC value, timestamps, and status. This object is always present; in case of errors, it contains default values.



In addition, there are Endpoint and Attribute string properties, identifying the source of the event. For a single OPC observable, they always contain the same value, but they become useful once you start combining events from different OPC sources into one stream.

12.2.3.5 Time in OPC and StreamInsight

In StreamInsight, the time that comes with events has to be monotonic, i.e. it cannot go back. More precisely, at the moment a CTI (Current Time Increment) event with certain time is stored into a stream, your application has committed to this point in time, and cannot store any events into the stream that have time that precedes the last CTI time. And, you must generate the CTI events, because before committing to certain time (by storing a CTI), StreamInsight cannot perform processing on the incoming stream events, because it does not know for sure that they represent the entirety of the information to be processed.

The time presents a challenge in many StreamInsight applications, and the combination of StreamInsight and OPC brings some additional points to consider. We try to present a summary of them below.

12.2.3.5.1 Time Synchronization in OPC

In OPC "Classic" (COM-based) specifications, such as OPC Data Access or OPC Alarms and Events, there is little or nothing specified about the times the OPC servers should use, and the timestamps that come with the OPC data. Specifically, there is no requirement that the OPC servers must have proper and synchronized time.

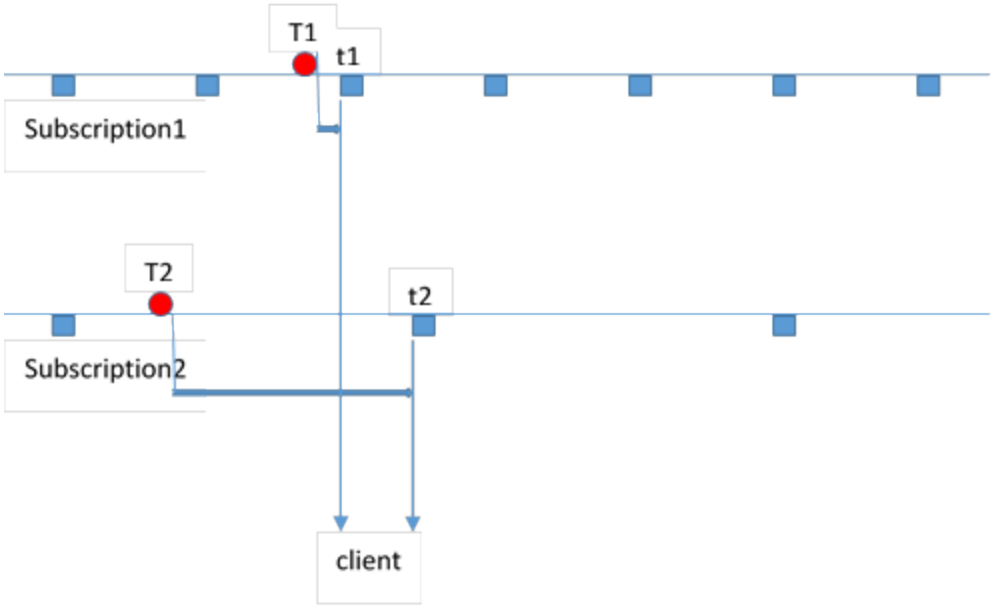
This becomes an issue when your application starts combining data from multiple OPC servers, and even more if they run on different computers. Unless you can guarantee their time synchronization by some application-specific means, you must assume that their times might be out of sync. Events that come in sequence from different servers may have their timestamps in decreasing order instead.

The OPC Unified Architecture specification has given more though to time, and (with some simplification), we may say that it requires the times be synchronized on both sides of the communication (between the OPC server and the OPC client), although it does not provide a mechanism to do, and again relies on external means to achieve.

The OPC-UA requirements consequently mean that if the OPC client (such as your application with StreamInsight Option for OPC Data Client) communicates with multiple OPC servers, all their times should be synchronized. In reality, however, not all systems will be set according to OPC specifications, and adding to that, the synchronization required by OPC-UA is not precise, and there may be several seconds' difference between the times on various computers. In StreamInsight, however, the time monotony requirement is a strict one – you cannot go back in time even by a fraction of a second.

12.2.3.5.2 Time in OPC Subscriptions

Even if the times used by all OPC servers were perfectly synchronized, one needs to consider how the OPC subscriptions are realized and what effect it has on the time monotony. In OPC, data change or event delivery is not usually immediate, for performance (throughput) reasons. Notifications are transferred in larger chunks, and only after certain time elapses, so that they can accumulate.



Let's have a look at following situation where we have two subscription, using different notification rates:

The red circles denote times when new source data appear. The blue squares denote times when the server delivers notifications to the client.

In this case, following occurrences happen in real time sequence:

1. At time T2, the new source data appear on Subscription2 (which has slower notification rate).
2. At time T1, the new source data appear on Subscription1 (which has faster notification rate).
3. At time t1, the data from Subscription1, carrying a T1 timestamp, are delivered to the client.
4. At time t2, the data from Subscription2, carrying a T2 timestamp, are delivered to the client.

As a result, the event that has appeared later (on T1) is delivered to the client earlier than the event that has appeared sooner (on T2). If the StreamInsight application wanted to use the timestamps of the source data, the time monotony requirement would be broken.

In addition, even with a single subscription, the OPC "Classic" server may send data with timestamps in reversed time order, albeit that would be quite rare and probably an indication of a buggy server.

12.2.3.5.3 Conclusions

The above findings can be summarized briefly as follows:

Microsoft StreamInsight has strict requirements on time monotony, which OPC cannot fulfill directly.

While the above statement may sound somewhat pessimistic, there are several ways how to adapt OPC times to StreamInsight, and we will mention some of them here. There is also material available from Microsoft and on the Web from various sources that deals with such issues, because other data sources that are used to feed events into StreamInsight deal with the same or similar issues.

Here are some options that can be used in various situations, either alone, or in combination:

- Use current system time on the client side for StreamInsight time, i.e. do not use OPC timestamps at all. This is the

approach used the in the simple examples shipped with the product, and in this document. The OPC timestamps become fields of the event payload, and can therefore have any valid value.
- You may use only single notification rate, or avoid combination of events from different sources before you advance the StreamInsight time.
- Use various AdvanceTimeSettings available in StreamInsight. For example, you may place an upper bound for how far back from the previous CTI the start time of the future event can be. Using AdvanceTimePolicy, you can also choose whether incoming events with start time before the current application time are dropped, or simply adjusted to the current application time.

The way that you resolve the issue of adapting OPC times to StreamInsight depends completely on the needs of your application, and there is no single approach that fits all applications.

12.2.4 StreamInsight Option Examples

The OPC Data Client installation contains usage examples for the StreamInsight Option in various programming languages. The examples are being updated and enhanced more frequently than the base product, so if you like them, please check for newer builds of OPC Data Client from time to time.

12.2.4.1 List of StreamInsight Option Examples

The examples assume an existence of a local StreamInsight instance named Instance1.

The examples are currently provided mainly for Microsoft Visual Studio 2017. They can all be automatically converted to later versions of Microsoft Visual Studio.

The examples are targeting Microsoft .NET Framework 4.7. In Visual Studio, it is possible to re-target the projects to newer framework versions (e.g. 4.7.2) by changing the appropriate setting in the properties of the project.

Visual Studio solution with examples in C# is available from the Start menu or the Launcher application.

	Visual C#	Visual Basic	Visual F#	Visual C++
SimpleAEStreamInsightApplication (Section 13.1.4.1.6): This example shows how to create an OPC Alarms&Events event source, and query it for events with severity 20 or higher.	✔			
SimpleDAStreamInsightApplication (Section 13.1.4.1.7): This example shows how to create an OPC Data Access event source, and query it for events carrying even data value.	✔			
SimpleUAStreamInsightApplication (Section 13.1.4.1.10): This example shows how to create an OPC Unified Architecture data event source, and query it for events carrying even data value.	✔			

12.2.5 StreamInsight Option Application Deployment

This chapter describes how to deploy applications developed with use of StreamInsight Option for OPC Data Client.

For application deployment, you need to consider a combination of rules that exist for OPC Data Client, and for

StreamInsight.

To properly deploy the OPC Data Client part, please refer to the “Application Deployment” chapter in this document. All information given there (for .NET) also applies to applications created with the StreamInsight Option for OPC Data Client. In Addition, you need to deploy the assemblies that are specific to the StreamInsight Option for OPC Data Client, but you do it in the same way as with other assemblies. You need to deploy one additional assembly:

- **OpcLabs.OpcComplexEventProcessing.dll**

For deploying the StreamInsight server, and the StreamInsight entities into a StreamInsight server, please see the appropriate StreamInsight documentation.

12.2.6 Additional Resources for StreamInsight Option

If you are migrating from earlier version, please read the “What’s New” document (available from the Start menu or the Launcher application).

Study the Reference documentation (also available from Start menu).

Explore the examples and bonus tools and materials installed with the product.

Check the vendor’s Web page for updates, news, related products and other information.

13 Examples

OPC Data Client comes with large number of examples, in multiple programming languages and tools.

Some of these examples are **installed with the product (Section 13.1)**, and some are **included in the documentation (Section 13.2)**. There is also a huge overlap - many (but not all) examples appear both in the product, and are also listed in the documentation. Examples that were written for the documentation are typically somewhat shorter pieces of code, to illustrate a specific point, and are included in the product installation for convenience. Larger standalone examples ship primarily with the product, but pieces of them has been includer in the documentation for easier understanding.

Additional examples can be found in the Knowledge Base.

We are continuously adding new examples, and extending our coverage of programming languages tools. If you think that an example is missing, let us know and we will try to add it.

13.1 Examples Installed with the Product

This documentation section consists of several parts:

- **COM Examples (Section 13.1.1)**, and
- **.NET Framework Examples (Section 13.1.2)**, and
- **.NET Standard Examples (Section 13.1.3)**, and
- **Copies of Selected Installed Examples (Section 13.1.4)**.

Depending on whether you develop OPC applications for Microsoft .NET, or are using Microsoft COM, please refer to the corresponding part.

Examples are provided for OPC "Classic" (COM-based) specifications, OPC XML-DA, and OPC Unified Architecture (OPC UA).

The OPC Data Client installation contains usage examples in various programming languages. The examples are being updated and enhanced more frequently than the base product, so if you like them, please check for newer builds of OPC Data Client from time to time.

Note that the examples are different for OPC Data Client.NET and OPC Data Client-COM. The text is marked with corresponding .NET or COM icon further below.

> For those who want to use the command-line interface, a "Command Prompt From Here" links are installed into example folders that are related to command prompt, such as JScript Examples in WSH, PHP Console Examples, and VBScript Examples in WSH (WIndows Script Host). These links allow you to switch from the Windows Explorer to a CMD window with the current directory set to the chosen place, for quick experiments and exploration.

13.1.1 COM Examples

The examples are provided to cover wide range of tools and languages used in development of industrial applications.

For OPC Data Access, the examples show:

- reading and writing OPC items,
- working with multiple items at once,
- error handling,
- subscribing for item changes, and managing subscriptions,
- getting property values,
- browsing for OPC servers, branches and leaves, and properties,
- obtaining information about OPC servers,
- processing events,
- user interface for browsing,
- and more.

For OPC Alarms and Events, the examples show:

- subscribing to events,
- event filtering,
- error handling,
- subscribing for item changes, and managing subscriptions,
- browsing for OPC servers, areas and sources,
- querying for event categories, conditions and attributes,
- obtaining information about OPC servers,
- processing events,
- acknowledging conditions,
- refreshing event subscriptions,
- and more.

For OPC Unified Architecture, the examples show:

- reading and writing attributes of OPC nodes,
- working with multiple nodes/attributes at once,
- error handling,
- subscribing for monitored item changes, and managing subscriptions,
- discovering OPC servers,
- browsing for OPC nodes,
- processing events,
- user interface for browsing,
- and more.

Following categories of COM examples are available , and corresponding shortcuts exist in the Start menu or the Launcher application:

- **Free Pascal Examples (Lazarus) (Section 13.1.1.1)**
- **JScript Examples (IE, WSH) (Section 13.1.1.2)**
- **Object Pascal Examples (Delphi) (Section 13.1.1.3)**
- **Perl Examples (Section 13.1.1.4)**
- **PHP Examples (Section 13.1.1.5)**
- **PowerScript Examples (PowerBuilder) (Section 13.1.1.6)**
- **Python Examples (Section 13.1.1.7)**
- **REALbasic (Xojo) Examples (Section 13.1.1.8)**
- **VBA Examples in Excel (Section 13.1.1.9)**
- **VBScript Examples (ASP, IE, WSH) (Section 13.1.1.10)**
- **Visual Basic Examples (VB 6.0) (Section 13.1.1.11)**

- Visual C++ Examples
- **Visual FoxPro Examples (Section 13.1.1.13)**
- Xbase++ Examples

13.1.1.1 Free Pascal Examples (Lazarus)

The examples are currently provided for Lazarus 1.6 (FPC 3.0).

- UADocExamples: Contains all Free Pascal examples for OPC-UA that are given in the Reference documentation.

13.1.1.2 JScript Examples (IE, WSH)

JScript Examples in IE

In This Topic

The examples here run inside Internet Explorer, i.e. directly on client. No Web server is required. The EasyOPC-DA component must be installed on the client side, and the OPC server(s) must be accessible locally or via DCOM from the computer where EasyOPC-DA component resides.

- ReadAndDisplayValue_JScript.htm: Reads and displays an OPC item value.

JScript Examples in WSH

The examples here run in Windows Script Host (WSH), e.g. from Windows Command Prompt.

- **DocExamples** folder: Contains all JScript examples for OPC Classic that are given in the Reference documentation.
- **ReadAndDisplayValue.js**: Reads and displays an OPC item value.
- **UADocExamples** folder: Contains all JScript examples for OPC-UA that are given in the Reference documentation.

> For those who want to use the command-line interface, a "Command Prompt From Here" link is installed into the examples folder. This link allows you to switch from the Windows Explorer to a CMD window with the current directory set to the chosen place, for quick experiments and exploration.

13.1.1.3 Object Pascal Examples (Delphi)

The examples in Object Pascal are currently provided for Delphi 10.3. In case you are not able to directly load the projects into earlier versions of Delphi, the actual source code is likely to work just well with no or minor modifications, so you just need to re-create the "envelope" project files.

In earlier versions, we have tested the examples with Delphi XE7, and also briefly with Delphi XE8 and Delphi 10 Seattle. In OPC Data Client 2019.2, we have tested the examples with Delphi 10.3 Rio (10.3.2).

- **DocExamples**: Contains all Delphi examples for OPC Classic that are given in the Reference documentation.
- **EasyOpcUADemo**: Shows how to make a desktop windowed OPC UA client application, mimicking the example

that is available in C# and VB.NET. The application demos the most important product functions, including event-based subscriptions.
- **Imports**: Contains Delphi components created by importing OPC Data Client type libraries.
- **ReadAndDisplayValue**: The simplest form. Reads and displays an OPC item value.
- **UADocExamples**: Contains all Delphi examples for OPC-UA that are given in the Reference documentation.

13.1.1.4 Perl Examples

The Perl examples were tested in ActivePerl v5.14.2.

- **ReadAndDisplayValue.pl**: The simplest console application for OPC "Classic". Reads and displays an OPC item value.
- **SubscribeToValue.pl**: Subscribes to changes of an OPC Classic item, and displays the values.
- **UAReadAndDisplayValue.pl**: The simplest console application for OPC UA. Reads and displays an OPC item value.
- **UASubscribeToValue.pl**: Subscribes to changes of an OPC UA monitored item, and displays the values.

13.1.1.5 PHP Examples

Various PHP versions can be downloaded from http://php.net/downloads.php . PHP for Windows is available from https://windows.php.net/download/ .

In some earlier versions, the examples were tested in PHP v5.6, under command-line interpreter and Internet Information Server (IIS). In OPC Data Client 2019.2, the examples were tested in PHP 7.3.10 (VC15 x64 Thread Safe).

In This Topic

The examples use the COM extension for PHP. This extension can be enabled e.g. in following ways:

a) Add following to the php.ini file:

```
extension=ext/php_com_dotnet.dll
```

b) Use following in the php.ini file:

```
extension_dir =  "ext"
extension=php_com_dotnet.dll
```

c) From IIS, under Internet Information Services (IIS) Manager, by PHP Manager: Use

```
[PHP_COM_DOTNET]
extension=php_com_dotnet.dll
```

PHP Console Examples

In order to run the command-line examples, use

```
PHP.EXE –f "filename"
```

For easier troubleshooting of the command-line scripts, it is recommended that you enable the display_error option, e.g. in one of the following ways:

a) Use the following on the command line:

-d display_errors

b) Add following to the php.ini file:

display_errors = On

c) Copy the file php.ini-development over your php.ini file.

The provided examples are:

- **Console\DocExamples** folder: Contains all command-line PHP examples for OPC Classic that are given in the Reference documentation.
- **Console\UADocExamples** folder: Contains all command-line PHP examples for OPC-UA that are given in the Reference documentation.

> For those who want to use the command-line interface, a "Command Prompt From Here" link is installed into the examples folder. This link allows you to switch from the Windows Explorer to a CMD window with the current directory set to the chosen place, for quick experiments and exploration.

PHP Web Examples

In order to run the Web-based examples, you need to configure an IIS virtual directory that points to the physical directory where the examples are installed.

Examples in this folder are Web server scripts: the page, including OPC data, is generated on the server. The EasyOPC component must be installed on the server side, and the OPC server(s) must be accessible locally or remotely from the computer where EasyOPC component resides.

- **Web\ReadAndDisplayValue.php**: The simplest Web application. Reads and displays an OPC item value.
- **Web\ReadAndDisplayMultipleItems.php**. Reads four values at once and displays their contents. Aimed at showing how PHP can pass input and output arguments that are VARIANT arrays.
- **Web\UADocExamples** folder: Contains all Web server PHP examples for OPC-UA that are given in the Reference documentation.

13.1.1.6 PowerScript Examples (PowerBuilder)

The PowerScript examples were developer and tested in Appeon PowerBuilder 2017 R3.

The QuickOpcPowerBuilderExamples workspace contains following targets:

- **DocExamples**: Contains all PowerBuilder examples for OPC Classic that are given in the Reference documentation.
- **UADocExamples**: Contains all PowerBuilder examples for OPC-UA that are given in the Reference documentation.

13.1.1.7 Python Examples

With some earlier OPC Data Client versions, the examples were tested in Python 3.4.2, with pywin32-219 extension (Build 219). With OPC Data Client 2018.3 and 2019.2, the examples were tested in Python 3.6 (64-bit), and pywin32 (223) extension.

- **DocExamples** folder: Contains all Python examples for OPC Classic that are given in the Reference documentation.
- **UADocExamples** folder: Contains all Python examples for OPC-UA that are given in the Reference documentation.

In C:\Python*XX*\Scripts, do:
`pip install pypiwin32`

13.1.1.8 REALbasic (Xojo) Examples

Note: We do not regularly update these examples with new versions. You may have to modify the code to use newer versions.

The REALbasic (Xojo) examples were originally created in REAL Studio 2010r5, and converted to REAL Studio 2011r1.1, and later versions.

- **Xojo2014\ReadAndDisplayValue.xojo_binary_project**: The simplest form, for OPC "Classic". Reads and displays an OPC item value.
- **Xojo2014\UAReadAndDisplayValue...**: The simplest form, for OPC UA. Reads and displays an OPC item value.

13.1.1.9 VBA Examples in Excel

VBA stands for Visual Basic for Applications. The examples were developed and tested in various Excel versions between Excel 2007 and Excel 2016, but are saved in Excel 2003 format for compatibility.

- **ReadAndDisplayMultipleValues.xls**: Reads multiple OPC Classic item values, and stores them in cells of a worksheet.
- **ReadAndDisplayValue.xls**: The simplest Excel VBA example for OPC "Classic". Reads an OPC item value and stores it in a cell of a worksheet.
- **ReadAndWriteValue.xls**: Shows how to read or write an OPC Classic item value upon press of a button.
- **SubscribeToMultipleItems.xls**: Show how to subscribe to and unsubscribe from multiple OPC Classic items, and how to continuously update the worksheet cells with their values.
- **UAClientCertificateParameters.xls**: Sets the application name for the client certificate.
- **UADataDialog.xls**: Shows how a user can interactively select an OPC-UA endpoint and a data node.
- **UAReadAndDisplayMultiple.xls**: Reads multiple OPC UA nodes, and shows the results in cells of a worksheet.
- **UAReadAndDisplayValue.xls**: The simplest Excel VBA example for OPC UA. Reads an OPC UA value and stores it in a cell of a worksheet.
- **UAReadAndWriteValue.xls**: Shows how to read or write an OPC UA value upon press of a button.
- **UASubscribeToMultiple.xls**: Shows how to subscribe to and unsubscribe from multiple OPC UA monitored items, and how to continuously update the worksheet cells with their values.
- **UASubscribeToMultiple2.xls** and **UASubscribeToMultiple3.xls**: As UASubscribeToMultiple.xls, but allows sheet editing while being subscribed, using different approaches. The UASubscribeToMultiple3.xls example also shows hoe to specify an absolute deadband.

Much, if not all, of the functionality presented by these examples is achievable without any programming using the **Excel Option (Section 12.1)**. You should only consider using VBA if the features provided by the Excel Option are not sufficient for your application.

13.1.1.10 VBScript Examples (ASP, IE, WSH)

VBScript Examples in ASP

These VBScript examples run in Internet Information Server (IIS). In order to run the examples, you need to configure an IIS virtual directory that points to the physical directory where the examples are installed.

Examples in this folder are Web server scripts: the page, including OPC data, is generated on the server. The EasyOPC component must be installed on the server side, and the OPC server(s) must be accessible locally or remotely from the computer where EasyOPC component resides.

The server must be in the Web Server (IIS) role, and in it, make sure you have the "Web Server -> Application Development -> ASP" role service.

- **ReadAndDisplayValue_VBScript.asp**: The simplest Web application. Reads and displays an OPC item value.

VBScript Examples in IE

The examples here run inside Internet Explorer (IE), i.e. directly on client. No Web server is required. The EasyOPC component must be installed on the client side, and the OPC server(s) must be accessible locally or remotely from the computer where EasyOPC component resides.

- **ReadAndDisplayValue_VBScript.htm**: Reads and displays an OPC item value.

VBScript Examples in WSH

The examples here run in Windows Script Host (WSH), e.g. from Windows Command Prompt.

It is possible to use CScript (console output) or WScript (window output) to run the examples. Some examples give longer output, and CScript is better for them as you do not have to confirm each “line” of output by pressing a button as in WScript.

- **APISimplifier.wsc**, **ReadUsingSimplifier.vbs**: Shows how to create and use a component that provides domain-specific API to OPC Data Client.
- **ReadAndDisplayValue.vbs**: Reads and displays an OPC item value.
- **DocExamples** folder: Contains all VBScript examples for OPC Classic that are given in the Reference documentation.
- **UADocExamples** folder: Contains all VBScript examples for OPC-UA that are given in the Reference documentation.

> For those who want to use the command-line interface, a "Command Prompt From Here" link is installed into the examples folder. This link allows you to switch from the Windows Explorer to a CMD window with the current directory set to the chosen place, for quick experiments and exploration.

13.1.1.11 Visual Basic Examples (VB 6.0)

The examples are for Visual Basic 6.0.

- **ReadAndDisplayValue**: The simplest form. Reads and displays an OPC item value. This is what you get if you

follow the steps described in Quick Start for OPC Data Client-COM.
- **SubscribeMultipleItems**: Subscribes to multiple OPC-DA items, and displays the incoming changes in the list box.
- **UADocExamples**: Contains all VB 6.0 examples for OPC-UA that are given in the Reference documentation.
- **UAReadAndDisplayValue**: The simplest form for OPC-UA. Reads and displays an OPC-UA node value.
- **WriteMultipleItemValues**: Writes different values to multiple OPC Data Access items at once.

13.1.1.12 Visual C++ Examples

The majority of Visual C++ examples are currently provided for Microsoft Visual Studio 2017, with a possible conversion to Microsoft Visual Studio 2019.

We also provide an example in Microsoft Visual Studio 6.0 (Visual C++ 6.0), to show the feasibility, although we do not regularly update it with newer version of OPC Data Client.

In This Topic

Examples in Visual Studio 2017+

- **MFC\EasyOPCDADemo**: This is a clone of the Demo application that ships with the OPC Data Client-COM product.

- **Win32\DumpAddressSpace**: Dumps OPC server's address space recursively to the console.
- **Win32\RandomReads**: Reads random number of random items in a random fashion. This example can serve as kind of a stress test.
- **Win32\ReadMultipleItems**: Reads multiple items, and displays the results.
- **Win32\ReadMultipleItemsXml**: Reads multiple items from an OPC XML-DA server, and displays the results.
- **Win32\SubscribeMultipleItems**: Subscribes to changes of multiple items and display the value of the item with each change.
- **Win32\UADocExamples**: Contains all C++ examples for OPC-UA that are given in the Reference documentation.
- **Win32\WriteMultipleItemValues**: Writes values into multiple items at once.

All examples #include (through **stdafx.h**) a **QuickOpc.h** file in the **SDK\include** subdirectory. This file imports all OPC Data Client type libraries and declares wrappers for OPC Data Client interfaces and classes.

> We cannot assure that the examples target one of the Windows SDK versions installed in your development computer. When opening or building the examples, you may receive a warning or error to this effect. The examples do not rely on particulars of any Windows SDK version, and you should be able to easily retarget them to the Windows SDK version of your wish. In Visual Studio, if the retargeting is not offered to you or performed automatically, right-click on the solution node in the **Solution Explorer**, select the Retarget solution command, and proceed as needed.

Examples in Visual Studio 6.0

You will find some more information to this subject in the Knowledge Base article .

- **Win32\ReadMultipleItems**: Reads multiple items, and displays the results.

All examples #include (through **stdafx.h**) a **QuickOpc.h** file in the **SDK\include** subdirectory. This file imports all OPC Data Client type libraries and declares wrappers for OPC Data Client interfaces and classes.

13.1.1.13 Visual FoxPro Examples

Note: We do not regularly update these examples with new versions. You may have to modify the code to use newer version numbers.

The examples were tested in Visual FoxPro 9.0 with Service Pack 2.

- **ReadItemValue**: Reads a value of an OPC Classic item and displays it in a message box.
- **UAReadItem**: Reads a value of an OPC UA node and displays it in a message box.

13.1.1.14 Xbase++ Examples

Note: We do not regularly update these examples with new versions. You may have to modify the code to use newer version numbers.

The examples were tested with Xbase++ 1.90 SL1.

- **UAReadValue.prg**: Reads a values of an OPC UA node displays it.
- **WriteAndReadValue.prg**: Writes a value into an OPC Classic item, reads it back and displays it.

13.1.2 .NET Framework Examples

> ⚠ This article applies only if you are targeting .NET Framework runtime. If you are targeting .NET Standard, refer to **.NET Standard Examples (Section 13.1.3)** instead.

In This Topic

The examples are currently provided for Microsoft Visual Studio 2017. They can all be automatically converted to Microsoft Visual Studio 2019.

The examples are targeting Microsoft .NET Framework 4.7 (and will also run under newer versions). In Visual Studio, it is possible to re-target the projects to newer framework versions (e.g. 4.8) by changing the appropriate setting in the properties of the project.

Visual Studio solutions with examples in Visual Basic, C#, F# and C++ are available from the **Start** menu or the **Launcher** application.

NuGet Packages

Some examples (those from the DocExamples and UADocExamples projects, in C# and VB.NET) are also distributed (with source code) in form of NuGet packages, on www.nuget.org . The packages are:

- **OpcLabs.QuickOpc.Sample.CS**: Console-based QuickOPC examples in C# (source code).
- **OpcLabs.QuickOpc.Sample.VB**: Console-based QuickOPC examples in VB.NET (source code).

The strings in **bold** are the package IDs.

Using The Example Packages

The Example Package is not a runnable project on its own. It just contains pieces of source code that you can call or copy into your own project.

In order to run the code from console-based example packages, you need to call it from your project. The examples are organized by the OPC specification, and each example is a static method that you can directly invoke. For easier exploration, there are also methods that provide the user with a menu of methods to choose from.

- For OPC Alarms&Events examples, call method: DocExamples.AlarmsAndEvents.AEExamplesMenu.Main1
- For OPC Data Access, call method: DocExamples.DataAccess.DAExamplesMenu.Main1
- For OPC Unified Architecture examples, call method: UADocExamples.UAExamplesMenu.Main1
- For OPC XML-DA examples, call method: DocExamples.DataAccess.Xml.XmlExamplesMenu.Main1

Alternatively, you can call just a single selected example, e.g. for reading an OPC UA node, call the UADocExamples._EasyUAClient.Read.Main1 method.

Example Archives

Most examples for .NET Framework can also be downloaded directly from the Web, without having to use the product installer, in form of archive (.ZIP) files. They are:

- C++ Examples for .NET Framework (ZIP file)
- C# Examples for .NET Framework (ZIP file)
- PowerShell Examples for .NET Framework (ZIP file)
- VB.NET Examples for .NET Framework (ZIP file)

Note: F# examples are only available for .NET Standard - see **.NET Standard Examples (Section 13.1.3)**. You can, however, use the same F# source files in .NET Framework, and recreate the example project in .NET Framework, if you need.

Categories

Following categories of .NET examples are available:

- **Examples for OPC "Classic" (OPC-DA, OPC XML-DA and OPC-A&E) (Section 13.1.2.1)**
- **Examples for OPC Unified Architecture (OPC-UA) (Section 13.1.2.2)**
- **Integration Examples (Section 13.1.2.3)**
- **Reactive Programming Examples (Section 13.1.2.4)**
- **LINQPad Examples (Section 13.1.2.5)**

13.1.2.1 Examples for OPC "Classic" (OPC-DA, OPC XML-DA and OPC-A&E)

Console Examples

In This Topic

	Visual C#	Visual Basic	Visual F#	Visual C++
ConsoleApplication1 (Section 13.1.4.1.1): The simplest console application. Reads and displays an OPC item value in a console.			✔	✔
ConsoleLiveMapping (Section 13.1.4.1.2): Creates an object structure for a boiler, describes its mapping into OPC Data Access server using attributes, and then performs the live mapping. Boiler data is then read, written and/or subscribed to using plain .NET object access.	✔	✔		
DocExamples: A collection of OPC "Classic" and OPC XML-DA console-based examples that illustrate the use of individual objects in the product, and their members. These are the same examples that appear in reference and conceptual documentation, with an extra control routine that allows the use to choose an example to be performed.	✔	✔		
LogAsStringToSql (Section 13.1.4.1.3): Logs OPC Data Access item changes into an SQL database, using a subscription.Values of all data types are stored in a single NVARCHAR column.	✔	✔		
LogAsUnionToSql (Section 13.1.4.1.4): Logs OPC Data Access item changes into an SQL database, using a subscription. Values of all data types are stored in separate columns.	✔	✔		
LogToSqlEnhanced (Section 13.1.4.1.5): Logs OPC Data Access item changes into an SQL database, using a subscription. Item values and qualities are stored in their respective columns. Notifications with the same timestamp are merged into a single row.	✔	✔		
SubscribeFromXml (Section 13.1.4.1.11): Loads list of OPC items from an XML file and subscribes to them.	✔	✔		
WcfClient1 (Section 13.1.4.1.14): Using a Web service provided by the WcfService1 project (under Web folder), gets and displays a value of an OPC item.	✔	✔		
XmlEventLogger (Section 13.1.4.1.15): Logs OPC Alarms and Events notifications into an XML file.	✔	✔		
XmlLogger (Section 13.1.4.1.16): Logs OPC Data Access item changes into an XML file.	✔	✔		

Web Examples

	Visual C#	Visual Basic	Visual F#	Visual C++
AutoRefreshWeb (Section 13.1.4.2.1): Web application with a screen that refreshes itself periodically.	✔	✔		
BrowseBranchesWeb (Section 13.1.4.2.2): Browses the branches in the OPC server (ASP.NET Web application).	✔	✔		
BrowseServersWeb (Section 13.1.4.2.3): Browses the available OPC servers (ASP.NET Web application).	✔	✔		
DataGridWebApplication (Section 13.1.4.2.4): Demonstrates how easily can WebControls.GridView be populated with data read from OPC Data Access server.	✔	✔		
WcfService1 (Section 13.1.4.2.6): A simple Web service using WCF technology. Provides a GetData method to read a value of an OPC item. Use WcfClient1 project (under Console folder) to test this Web service.	✔	✔		
WebApplication1 (Section 13.1.4.2.7): The simplest ASP.NET Web application for OPC "Classic". Reads and displays an OPC item value.	✔	✔		
WebService1 (Section 13.1.4.2.8): A simple Web service using ASMX technology. Provides "Hello World" method to read a value of an OPC item.	✔	✔		

Windows Forms Examples

	Visual C#	Visual Basic	Visual F#	Visual C++
EasyOpcNetDemo (Section 13.1.4.3.1): This is a source of the Demo application for OPC "Classic" that ships with the OPC Data Client.NET product. The application shows most product functions, including the browsing forms, OPC property access, and event-based subscriptions.	✔	✔		
EasyOpcNetDemoXml (Section 13.1.4.3.2): This is a source of the Demo application for OPC "Classic" (OPC XML-enabled) that ships with the OPC Data Client.NET product. The application shows most product functions, including the browsing forms, OPC property access, and event-based subscriptions. The defaults are pre-filled for OPC XML-DA demo server, but the application is written in such a way that it can handle COM servers as well.	✔			
HmiScreen (Section 13.1.4.3.4): Windows Forms application that shows how to use implement an HMI screen by storing OPC Item IDs in the Tag property of screen controls, and animate the controls by subscribing to all items at once. Also shows a possibility how to write to an OPC item form the screen.	✔	✔		
ListView1: Shows how (Windows Forms) ListView items can be populated with OPC data, either using explicit Read, or with a subscription.		✔		
LiveBindingDemo: Shows live binding of OPC Data Access information (from simulation	✔	✔		

	Visual C#	Visual Basic	Visual F#	Visual C++
OPC server) to standard Windows Forms controls (Microsoft). All binding to OPC data is achieved with no manual coding, only by configuring the components in Visual Studio. 				
LiveBindingDemo2: Shows advanced live binding features. Among others, it demonstrates: · Binding kinds: binding to local vs. UTC timestamp. · Conversions: Use of LinearConverter, even bi-directionally. · Animations: Moving a control around the form, depending on an OPC tag value. · Cumulative: Adding incoming values to ListBox or ListView.	✔			
OvenControl (Section 13.1.4.3.5): Monitors sensors in an industrial oven, indicates level alarms by changing colors, allows the user to change a setpoint, and logs the values into a CSV file.	✔	✔		
QualityStrings (Section 13.1.4.3.6): Shows how numerical OPC quality codes are converted to displayable strings (Windows Forms application).	✔	✔		
SimpleLogToSql (Section 13.1.4.1.8): Logs OPC Data Access item changes into an SQL database, using a subscription.Values of all data types are stored in a single SQL_VARIANT column.	✔	✔		
SubscribeToMany (Section 13.1.4.3.7): Demonstrates and measures performance with large number of subscribed OPC items.	✔	✔		
ValueToMessageBox (Section 13.1.4.3.8): Very simple Windows Forms application that reads and displays an OPC item value in a message box after the user clicks on a button.	✔	✔		
WindowsFormsApplication1 (Section 13.1.4.3.9): The simplest Windows Forms application. Reads and displays an OPC item value on a form. This is what you get if you follow the steps described in Quick Start for OPC Data Client.NET.	✔	✔		

Windows Service Examples

	Visual C#	Visual Basic	Visual F#	Visual C++
WindowsService1 (Section 13.1.4.4.1): A Windows Service that subscribes to items from the simulation server, and logs their changes into a file.	✔	✔		

WPF Examples

	Visual C#	Visual Basic	Visual F#	Visual C++
OpcDAQualityDecoder (Section 13.1.4.5.1): A simple WPF application that decodes the cryptic OPC quality numbers into the separate fields and their symbolic representation.	✔			
WpfApplication1 (Section 13.1.4.5.3): The simplest WPF application for OPC "Classic". Reads and displays an OPC item value.	✔			

13.1.2.2 Examples for OPC Unified Architecture (OPC-UA)

Console Examples

In This Topic

	Visual C#	Visual Basic	Visual F#	Visual C++
UAConsoleApplication1: The simplest console application. Reads and displays an OPC-UA node value in a console.			✔	
UADocExamples: A collection of OPC-UA console-based examples that illustrate the use of individual objects in the product, and their members. These are the same examples that appear in reference and conceptual documentation, with an extra control routine	✔	✔	✔	

	Visual C#	Visual Basic	Visual F#	Visual C++
that allows the use to choose an example to be performed. Note: The amount of available example material may differ between the languages.				
UAConsoleLiveMapping (Section 13.1.4.1.12): Creates an object structure for a boiler, describes its mapping into OPC Unified Architecture server using attributes, and then performs the live mapping. Boiler data is then read, written and/or subscribed to using plain .NET object access.	✔	✔		
UASimpleLogToSql (Section 13.1.4.1.13): Logs OPC Unified Architecture data changes into an SQL database, using a subscription. Values of all data types are stored in a single SQL_VARIANT column.	✔			

Web Examples

	Visual C#	Visual Basic	Visual F#	Visual C++
UAWebApplication1 (Section 13.1.4.2.5): The simplest ASP.NET Web application for OPC-UA. Reads and displays a value of a node in an OPC-UA server.	✔	✔		

Windows Forms Examples

	Visual C#	Visual Basic	Visual F#	Visual C++
EasyOpcUADemo (Section 13.1.4.3.3): This is a source of the Demo application for OPC-UA that ships with the OPC Data Client-UA product. The application shows the most important product functions, including event-based subscriptions.	✔	✔		
UALiveBindingDemo: Shows live binding of OPC Unified Architecture information (from sample OPC-UA server) to standard Windows Forms controls (Microsoft). All binding to OPC-UA data is achieved with no manual coding, only by configuring the components in Visual Studio.	✔	✔		

	Visual C#	Visual Basic	Visual F#	Visual C++
				

Windows Service Examples

	Visual C#	Visual Basic	Visual F#	Visual C++

WPF Examples

	Visual C#	Visual Basic	Visual F#	Visual C++
UAWpfScreen (Section 13.1.4.5.2): Shows how to update WPF controls with dynamic OPC-UA data.	✔			
WpfLiveBindingDemo: Shows live binding of OPC Data Access information (from simulation OPC server) to standard Windows Presentation Foundation (WPF) controls (Microsoft). All binding to OPC data is achieved with no manual coding, only by configuring the components in Visual Studio.	✔			

13.1.2.3 Integration Examples

These examples show how OPC Data Client can be integrated with products from other parties.

	Visual C#	Visual Basic	Visual F#	Visual C++
IndustrialGadgetsDemo: Shows live binding of OPC Data Access items (from simulation OPC server) to controls from Industrial Gadgets .NET (a separate product, http://www.industrialgadgets.net/). The application has been developed with no manual coding - all functionality is achieved by configuring the components in Visual Studio. 	✔	✔		
InstrumentationControlsDemo: Shows live binding of OPC Data Access items (from simulation OPC server) to controls from Instrumentation .NET (a separate product, http://www.instrumentationopc.com/). The binding is done with no manual coding - all functionality is achieved by configuring the components in Visual Studio. 	✔	✔		
SymbolFactoryDemo: Shows live binding of OPC Data Access items (from simulation OPC server) to controls from Symbol Factory .NET (a separate product, http://www.symbolfactory.net/). All controls are bound to a single source item. The application has been developed with no manual coding - all functionality is achieved by configuring the components in Visual Studio.	✔	✔		

	Visual C#	Visual Basic	Visual F#	Visual C++
				

13.1.2.4 Reactive Programming Examples

Examples for reactive programming model need an installation of Microsoft Reactive Extensions for proper building. These extensions are now provided by Microsoft in the form of NuGet packages.

The examples only contain references to the additional packages needed, and not the packages themselves. With the help of automatic NuGet Package Restore feature (http://docs.nuget.org/docs/reference/package-restore), when enabled, the missing packages will automatically be downloaded and installed when you first build the project that references them.

In Visual Studio, this works “out of the box” (with default settings). If building the project in Visual Studio fails due to missing NuGet packages, you may have the automatic NuGet package restore turned off. Check your Visual Studio settings.

	Visual C#	Visual Basic	Visual F#	Visual C++
ReactiveDocExamples: A collection of console-based examples for reactive programming model that illustrate the use of individual objects in the product, and their members. These are the same examples that appear in reference documentation, with an extra control routine that allows the use to choose an example to be performed.	✔			

13.1.2.5 LINQPad Examples

We have created and tested LINQPad examples with LINQPad 5. They might work under LINQPad 4 as well.

You will find LINQPad examples under the CSharp, FSharp and VBNET directories in the examples, always under the LINQPad5 subdirectory. They are available in form of LINQPad sample library (.zip file). This allows you conveniently see the examples organized in a hierarchical structure, and select them quickly. In order to use the sample library from LINQPad, switch to the “Samples” tab in the lower left part of LINQPad, click "Download/import more samples...” in the tree view, and then click the “Browse...” link in the bottom left corner, and navigate to the .zip file from OPC Data Client.

In addition, the same LINQPad examples are included with the NuGet packages of OPC Data Client. This means that whenever you reference one of the OPC Data Client NuGet packages in LINQPad, LINQPad will automatically add the OPC

Data Client examples under its “Samples” tab.

13.1.3 .NET Standard Examples

The examples are currently created with Microsoft Visual Studio 2017, and can also be used with .NET Core CLI Tools, JetBrain Rider, and Visual Studio Code. They are likely to work with other development tools as well, but we have not tested it.

On Windows, if you have used the **Setup Program (Section 3.1.1)** to install OPC Data Client, Visual Studio solutions with examples in C# and F# are available from the **Start** menu or the **Launcher** application. On other platforms (when you are simply installing the OPC Data Client **NuGet Packages (Section 3.1.2)**), you are advised to download the example archives from the Web and unpack them on your computer. This is described further below.

In This Topic

Example Archives

Examples for .NET Standard can be downloaded directly from the Web, in form of archive (.TGZ or .ZIP) files. This is the primary distribution method, which can be used without running any installer, on all operating systems. The archive files available are:

- C# examples for .NET Core:
  - TGZ file: http://cdn.opclabs.com/files/downloads/QuickOpc/2020.2/Examples-NETCore-CSharp.tgz, and
  - ZIP file: http://cdn.opclabs.com/files/downloads/QuickOpc/2020.2/Examples-NETCore-CSharp.zip
- F# examples for .NET Core:
  - TGZ file: http://cdn.opclabs.com/files/downloads/QuickOpc/2020.2/Examples-NETCore-FSharp.tgz, and
  - ZIP file: http://cdn.opclabs.com/files/downloads/QuickOpc/2020.2/Examples-NETCore-FSharp.zip

⚠ The examples are delivered in source form only. If you want to run them, having installed the proper .NET runtime is not enough - you also need the corresponding SDK. For .NET Core: Linux instructions, Windows instructions - make sure you install ".NET Core SDK" and not just "Runtime".

Retrieving the Example Archives

In order to use the example archives, first download them to your system, and extract the files from the archive. With a GUI on Windows, you can download the files using a Web browser, and uncompress the .ZIP with built-in Windows Explorer (shell) commands. You may have similar features on your Linux, depending on what distribution you chose. If you don't, following commands can be used in the terminal to download and extract the archives (the URL and file names are just examples - replace them with the right ones if you need a different set of examples):

```
wget "http://cdn.opclabs.com/files/downloads/QuickOpc/2020.2/Examples-NETCore-CSharp.tgz"
tar -xvzf Examples-NETCore-CSharp.tgz
```

On systems where **wget** is not available, you can use `curl -O` instead.

Working with the Examples

You can now open the solutions or projects from your IDE, view and modify their code, or run them.

If you just want to run the examples from the command line without inspecting their source code, first change your current directory to the project type of your choice, e.g.:

cd Console

Then, build and launch the chosen project, e.g.:

dotnet run --project UADocExamples/MultiTargetUADocExamples.csproj

or

dotnet run --project DocExamples/MultiTargetDocExamples.csproj

⚠ All OPC Data Client project files for .NET Standard start with prefix **"MultiTarget"**. This is because there is also a second project over the same set of source files for .NET Framework, and a separate project file is needed for .NET Standard due to differences in the project format. Make sure you do not confuse the two projects. For example, in .NET Standard, use **"MultiTargetUADocExamples.csproj"**, and not **"UADocExamples.csproj"**.

Example NuGet Package

Some examples (those from the DocExamples and UADocExamples projects, in C#) are also distributed (with source code) in form of a NuGet package, on www.nuget.org . The package is:

- **OpcLabs.QuickOpc.Sample.CS**: Console-based QuickOPC examples in C# (source code).

The string in **bold** is the package ID.

The example NuGet package also contains code for OPC "Classic" specifications. This code is for .NET Framework only, and the only parts of it that will work under .NET Standard are those for the OPC XML-DA specification. You can dimply delete the folders that are not of interest to you from your project.

Using the Example NuGet Packages

The Example Package is not a runnable project on its own. It just contains pieces of source code that you can call or copy into your own project.

In order to run the code from console-based example packages, you need to call it from your project. The examples are organized by the OPC specification, and each example is a static method that you can directly invoke. For easier exploration, there are also methods that provide the user with a menu of methods to choose from.

- For OPC Unified Architecture examples, call method: UADocExamples.UAExamplesMenu.Main1
- For OPC XML-DA examples, call method: DocExamples.DataAccess.Xml.XmlExamplesMenu.Main1

Alternatively, you can call just a single selected example, e.g. for reading an OPC UA node, call the UADocExamples._EasyUAClient.Read.Main1 method.

Examples by Project Type

Console Application

	Visual C#	Visual F#
MultiTargetDocExamples: A collection of OPC XML-DA console-based examples that illustrate the use of individual objects in the product, and their members. These are the same examples that appear in reference and conceptual documentation, with an extra control routine that allows the use to choose an example to be performed. Note: The amount of available example material may differ between the languages.	✔	
MultiTargetUADocExamples: A collection of OPC-UA console-based examples that illustrate the use of individual objects in the product, and their members. These are the same examples that appear in reference and conceptual documentation, with an extra control routine that allows the use to choose an example to be performed. Note: The amount of available example material may differ between the languages.	✔	✔

13.1.4 Copies of Selected Installed Examples

This documentation section contains copies of selected examples that are installed with the product.

13.1.4.1 Installed Examples - Console

13.1.4.1.1 Installed Examples - Console - ConsoleApplication1

The simplest console application. Reads and displays an OPC item value in a console.

The main program:

C++/CLI

```
// $Header: $
// Copyright (c) CODE Consulting and Development, s.r.o., Plzen. All rights reserved.
// ConsoleApplication1.cpp : main project file.

#include "stdafx.h"

using namespace OpcLabs::EasyOpc::DataAccess;
using namespace System;

int main(array<System::String ^> ^args)
{
    EasyDAClient^ client = gcnew EasyDAClient();
    Console::WriteLine("Reading item...");
    // ReadItemValue is an extension method on the IEasyDAClient interface; need to
call it explicitly in C++/CLR.
    Console::WriteLine(IEasyDAClientExtension::ReadItemValue(client, "",
"OPCLabs.KitServer.2", "Demo.Ramp"));
    Console::WriteLine("Press Enter to continue...");
    Console::ReadLine();
    return 0;
}
```

13.1.4.1.2 Installed Examples - Console - ConsoleLiveMapping

Creates an object structure for a boiler, describes its mapping into OPC Data Access server using attributes, and then performs the live mapping. Boiler data is then read, written and/or subscribed to using plain .NET object access.

The main program:

C#

```
// ConsoleLiveMapping: Creates an object structure for a boiler, describes its mapping
into OPC Data Access server using
// attributes, and then performs the live mapping. Boiler data is then read, written
and/or subscribed to using plain .NET
// object access.

using System;
using System.Diagnostics;
using System.Threading;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.LiveMapping;
using OpcLabs.EasyOpc.DataAccess.LiveMapping.Extensions;

namespace ConsoleLiveMapping
{
    class Program
    {
        static void Main()
        {
            Console.WriteLine();
            Console.WriteLine("Mapping our data structures to OPC...");
            var mapper = new DAClientMapper();
            var boiler1 = new Boiler();
            mapper.Map(boiler1, new DAMappingContext
                {
                    ServerDescriptor = "OPCLabs.KitServer.2",   // local OPC server
                    // The NodeDescriptor below determines where in the OPC address
space we want to map our data to.
                    NodeDescriptor = new DANodeDescriptor { BrowsePath =
"/Boilers/Boiler #1"},
                    GroupParameters = 1000,  // requested update rate (for
subscriptions)
                });

            Console.WriteLine();
            Console.WriteLine("Reading all data of the boiler...");
            mapper.Read();
            Console.WriteLine("Drum level is: {0}",
boiler1.Drum.LevelIndicator.Output);

            Console.WriteLine();
            Console.WriteLine("Writing new setpoint value...");
            boiler1.LevelController.SetPoint = 50.0;
            Debug.Assert(boiler1.LevelController != null);
```

```
            mapper.WriteTarget(boiler1.LevelController, /*recurse:*/false);

            Console.WriteLine();
            Console.WriteLine("Subscribing to boiler data changes...");
            mapper.Subscribe(/*active:*/true);

            Thread.Sleep(30 * 1000);

            Console.WriteLine();
            Console.WriteLine("Unsubscribing from boiler data changes...");
            mapper.Subscribe(/*active:*/false);

            Console.WriteLine();
            Console.WriteLine("Press Enter to continue...");
            Console.ReadLine();
        }
    }
}
```

VB.NET

```

13.1.4.1.5 Installed Examples - Console - LogToSqlEnhanced

Logs OPC Data Access item changes into an SQL database, using a subscription. Item values and qualities are stored in their respective columns. Notifications with the same timestamp are merged into a single row.

The main program:

C#

```
// LogToSqlEnhanced: Logs OPC Data Access item changes into an SQL database, using a
subscription. Item values and qualities
// are stored in their respective columns. Notifications with the same timestamp are
merged into a single row.

// The database creation script is in the ExamplesNet\MSSQL\QuickOPCExamples.sql file
under the product installation
// directory. The example assumes that the database is already created.

    End Sub
End Class
```

13.1.4.2.6 Installed Examples - Web - WcfService1

A simple Web service using WCF technology. Provides a GetData method to read a value of an OPC item. Use WcfClient1 project (under Console folder) to test this Web service.

The service class:

C#

```
// WcfService1: A simple Web service using WCF technology. Provides a GetData method to
read a value of an OPC item.
// Use WcfClient1 project (under Console folder) to test this Web service.

using OpcLabs.EasyOpc.DataAccess;

namespace WcfService1
{
    // NOTE: If you change the class name "Service1" here, you must also update the
reference to "Service1" in Web.config and in the associated .svc file.
    public class Service1 : IService1
    {
```

```
        public string GetData()
        {
            var client = new EasyDAClient();
            object value = client.ReadItemValue("", "OPCLabs.KitServer.2",
"Demo.Ramp");
            return (value == null) ? "" : value.ToString();
        }
    }
}
```

VB.NET

```
' WcfService1: A simple Web service using WCF technology. Provides a GetData method to
read a value of an OPC item.
' Use WcfClient1 project (under Console folder) to test this Web service.
Imports OpcLabs.EasyOpc.DataAccess

13.1.4.3.4 Installed Examples - WindowsForms - HmiScreen

Windows Forms application that shows how to use implement an HMI screen by storing OPC Item IDs in the Tag property of screen controls, and animate the controls by subscribing to all items at once. Also shows a possibility how to write to an OPC item form the screen.

The form:

13.1.4.3.6 Installed Examples - WindowsForms - QualityStrings

Shows how numerical OPC quality codes are converted to displayable strings (Windows Forms application).

The form:

C#

```
using OpcLabs.EasyOpc.DataAccess;

namespace QualityStrings
{
    public partial class Form1
    {

        // ReSharper disable once NotNullMemberIsNotInitialized
        internal Form1()
        {
            InitializeComponent();
        }
        // ReSharper disable InconsistentNaming
        private void Form1_Load(object sender, System.EventArgs e)
```

```
        // ReSharper restore InconsistentNaming
        {
            //define the quality codes that we want to run thru our function as a test
            var qualityTests = new [] {0, 10, 50, 64, 100, 128, 150, 192, 210};

            //now test each of the quality codes defined above
            foreach (int qualityTest in qualityTests)
            {
                ListBox1.Items.Add(new DAQuality(qualityTest));
            }
        }

    private static Form1 _defaultInstance;
    public static Form1 DefaultInstance
    {
        get
        {
            // ReSharper disable ConvertIfStatementToNullCoalescingExpression

End Namespace
```

13.1.4.3.8 Installed Examples - WindowsForms - ValueToMessageBox

Demonstrates and measures performance with large number of subscribed OPC items.

The form:

C#

```
// $Header: $
// Copyright (c) CODE Consulting and Development, s.r.o., Plzen. All rights reserved.
using System;
using System.Windows.Forms;
using OpcLabs.EasyOpc.DataAccess;
```

```
namespace ValueToMessageBox
{
    public partial class Form1 : Form
    {
        public Form1()
        {
            InitializeComponent();
        }

        // ReSharper disable InconsistentNaming
        private void button1_Click(object sender, EventArgs e)
        // ReSharper restore InconsistentNaming
        {
            // Create EasyOPC-DA component
            var client = new EasyDAClient();

            // Read item value and display it in a message box
            object value = client.ReadItemValue("", "OPCLabs.KitServer.2",
"Demo.Single");
            if (value != null)
                MessageBox.Show(value.ToString());
        }
    }
}
```

VB.NET

```
' $Header: $
' Copyright (c) CODE Consulting and Development, s.r.o., Plzen. All rights reserved.
Imports OpcLabs.EasyOpc.DataAccess

Public Class Form1

    ' ReSharper disable InconsistentNaming
    Private Sub Button1_Click(ByVal sender As System.Object, ByVal e As EventArgs)
Handles Button1.Click
        ' ReSharper restore InconsistentNaming

        ' Create EasyOPC-DA component
        Dim easyDaClient As New OpcLabs.EasyOpc.DataAccess.EasyDAClient

        ' Read item value and display it in a message box
        MessageBox.Show(easyDaClient.ReadItemValue("", "OPCLabs.KitServer.2",
"Demo.Single"))
    End Sub
End Class
```

13.1.4.3.9 Installed Examples - WindowsForms - WindowsFormsApplication1

The simplest Windows Forms application. Reads and displays an OPC item value on a form. This is what you get if you follow the steps described in Quick Start for OPC Data Client.NET.

The form:

C#

```
// $Header: $
// Copyright (c) CODE Consulting and Development, s.r.o., Plzen. All rights reserved.
using System;
using System.Windows.Forms;
using OpcLabs.EasyOpc.DataAccess;

namespace WindowsFormsApplication1
{
    public partial class Form1 : Form
    {
        // ReSharper disable once NotNullMemberIsNotInitialized
        public Form1()
        {
            InitializeComponent();
        }

        // ReSharper disable InconsistentNaming
        private void Form1_Load(object sender, EventArgs e)
        // ReSharper restore InconsistentNaming
        {
            object value = easyDAClient1.ReadItemValue("", "OPCLabs.KitServer.2",
"Demo.Single");
            textBox1.Text = (value == null) ? "" : value.ToString();
        }
    }
}
```

VB.NET

```
' $Header: $
' Copyright (c) CODE Consulting and Development, s.r.o., Plzen. All rights reserved.
Imports OpcLabs.EasyOpc.DataAccess

Public Class Form1

    ' ReSharper disable InconsistentNaming
    Private Sub Form1_Load(ByVal sender As System.Object, ByVal e As EventArgs) Handles
MyBase.Load
        ' ReSharper restore InconsistentNaming

        TextBox1.Text = EasyDAClient1.ReadItemValue("", "OPCLabs.KitServer.2",
"Demo.Single")
    End Sub
End Class
```

13.1.4.4 Installed Examples - WindowsService

13.1.4.4.1 Installed Examples - WindowsService - WindowsService1

A Windows Service that subscribes to items from the simulation server, and logs their changes into a file.

The service:

C#

```
// WindowsService1: A Windows Service that subscribes to items from the simulation
server, and logs their changes into
// a file.

// Install the service by running:
//      C:\Windows\Microsoft.NET\Framework\v2.0.50727\InstallUtil.exe /i
WindowsService1.exe
// If you get "Access denied" error when starting the service, change its configuration
to run under Local System account.

using System;
using System.Diagnostics;
using System.IO;
using System.ServiceProcess;
using JetBrains.Annotations;
using OpcLabs.EasyOpc.DataAccess;
using OpcLabs.EasyOpc.DataAccess.OperationModel;

namespace WindowsService1
{
    public partial class Service1 : ServiceBase
    {
        const string FilePath = "C:\\Service1.txt";

        // ReSharper disable once NotNullMemberIsNotInitialized
        public Service1()
        {
            InitializeComponent();
        }

        protected override void OnStart(string[] args)
        {
            File.Create(FilePath).Close();

            easyDAClient1.SubscribeMultipleItems(
                new[]
                    {
                        new DAItemGroupArguments("", "OPCLabs.KitServer.2",

```

13.1.4.5 Installed Examples - WPF

13.1.4.5.1 Installed Examples - WPF - OpcDaQualityDecoder

A simple WPF application that decodes the cryptic OPC quality numbers into the separate fields and their symbolic representation.

The service:

C#

```
using OpcLabs.EasyOpc.DataAccess;
using System;
using System.Windows;
```

```
namespace OpcDAQualityDecoder
{
    /// <summary>
    /// Interaction logic for Window1.xaml
    /// </summary>
    public partial class Window1
    {
        public Window1()
        {
            InitializeComponent();
        }

        // ReSharper disable InconsistentNaming
        private void DecodeButton_Click(object sender, RoutedEventArgs e)
        // ReSharper restore InconsistentNaming
        {
            int value = Convert.ToUInt16(valueTextBox.Text);
            var quality = new DAQuality(value);

            qualityChoiceStringTextBox.Text = quality.QualityChoiceBitField.ToString();
            statusStringTextBox.Text = quality.StatusBitField.ToString();
            limitStringTextBox.Text = quality.LimitBitField.ToString();
        }
    }
}
```

13.1.4.5.2 Installed Examples - WPF - UAWpfScreen

Shows how to update WPF controls with dynamic OPC-UA data.

The service:

C#

```
using System.Windows;
using System.Windows.Controls;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.OperationModel;

namespace UAWpfScreen
{
    /// <summary>
    /// Interaction logic for MainWindow.xaml
    /// </summary>
    public partial class MainWindow/* : Window*/
    {
        public MainWindow()
        {
            InitializeComponent();
        }

        private void ClientOnDataChangeNotification(object sender,
```

```
EasyUADataChangeNotificationEventArgs eventArgs)
        {
            // We have passed in a reference to the target TextBox as the State
property in EasyUAMonitoredItemArguments.
            var textBox = (TextBox) eventArgs.Arguments.State;

            if (eventArgs.Succeeded)
                textBox.Text = eventArgs.AttributeData.DisplayValue();
            else
                textBox.Text = "*** Error: " + eventArgs.Exception;
        }

        private void Window_Loaded(object sender, RoutedEventArgs e)
        {
            // Define the target controls, the OPC data we want to monitor, and how
fast.
            var arguments = new []
            {
                new EasyUAMonitoredItemArguments(TextBox1, "http://opcua.demo-
this.com:51211/UA/SampleServer", "nsu=http://test.org/UA/Data/;i=10845", 1000),
                new EasyUAMonitoredItemArguments(TextBox2, "http://opcua.demo-
this.com:51211/UA/SampleServer", "nsu=http://test.org/UA/Data/;i=10853", 1000),
                new EasyUAMonitoredItemArguments(TextBox3, "http://opcua.demo-
this.com:51211/UA/SampleServer", "nsu=http://test.org/UA/Data/;i=10855", 1000)
            };

            // Hook the event handler, and subscribe to OPC data
            _client.DataChangeNotification += ClientOnDataChangeNotification;
            _handles = _client.SubscribeMultipleMonitoredItems(arguments);
        }

        private void Window_Unloaded(object sender, RoutedEventArgs e)
        {
            // Unsubscribe from OPC data, and unhook the event handler
            _client.UnsubscribeMultipleMonitoredItems(_handles);
            _client.DataChangeNotification -= ClientOnDataChangeNotification;
        }

        private readonly EasyUAClient _client = new EasyUAClient();

        private int[] _handles;
    }
}
```

13.1.4.5.3 Installed Examples - WPF - WpfApplication1

The simplest WPF application for OPC “Classic”. Reads and displays an OPC item value.

The service:

C#

```
using System.Windows;
```

```
using OpcLabs.EasyOpc.DataAccess;

namespace WpfApplication1
{
    /// <summary>
    /// Interaction logic for MainWindow.xaml
    /// </summary>
    public partial class MainWindow/* : Window*/
    {
        public MainWindow()
        {
            InitializeComponent();
        }

        private void Window_Loaded(object sender, RoutedEventArgs e)
        {
            var client = new EasyDAClient();
            var value = client.ReadItemValue("", "OPCLabs.KitServer.2", "Demo.Single");
            TextBox1.Text = (value== null) ? "" : value.ToString();
        }
    }
}
```

13.2 Examples in the Documentation (List)

This documentation section contains a list of all examples included directly in the documentation.

> Only examples that are able to "stand alone", i.e. have a function of their own that can be individually described and demonstrated, are listed. Small code snippets that only form a part of a larger article are not considered for this index.

  - **Examples - OPC Alarms&Events - Callback using a lambda (Section 13.2.3.5)**

13.2.1 Examples - Licensing

13.2.1.1 Examples - Licensing - Obtain serial number

The example below shows how to obtain the serial number of the active license, and determine whether it is a demo or trial license.

C#

```
// Shows how to obtain the serial number of the active license, and determine whether
it is a stock demo or trial license.

using System;
using OpcLabs.EasyOpc.UA;

namespace UADocExamples.Licensing
{
    class LicenseInfo
    {
        public static void SerialNumber()
        {
```

```
            // Instantiate the client object.
            var client = new EasyUAClient();

            // Obtain the serial number from the license info.
            long serialNumber = (uint)client.LicenseInfo["Multipurpose.SerialNumber"];

            // Display the serial number.
            Console.WriteLine("SerialNumber: {0}", serialNumber);

            // Determine whether we are running as demo or trial.
            if ((1111110000 <= serialNumber) && (serialNumber <= 1111119999))
                Console.WriteLine("This is a stock demo or trial license.");
            else
                Console.WriteLine("This is not a stock demo or trial license.");
        }
    }
}
```

Object Pascal

```
// Shows how to obtain the serial number of the active license, and determine whether
it is a stock demo or trial license.

class procedure LicenseInfo.SerialNumber;
var
  Client: _EasyUAClient;
  SerialNumber: Int64;
begin
  // Instantiate the client object
  Client := CoEasyUAClient.Create;

  // Obtain the serial number from the license info.
  SerialNumber := Int64(client.LicenseInfo['Multipurpose.SerialNumber']);

  // Display the serial number.
  WriteLn('SerialNumber: ', SerialNumber);

  // Determine whether we are running as demo or trial.
  if ((1111110000 <= SerialNumber) and (SerialNumber <= 1111119999)) then
    WriteLn('This is a stock demo or trial license.')
  else
    WriteLn('This is not a stock demo or trial license.');
end;
```

PHP

```
// This example shows how to obtain nodes under a given node of the OPC-UA address
space.
// Shows how to obtain the serial number of the active license, and determine whether
it is a stock demo or trial license.

// Instantiate the client object
$Client = new COM("OpcLabs.EasyOpc.UA.EasyUAClient");

// Obtain the serial number from the license info.
$SerialNumber = $Client->LicenseInfo["Multipurpose.SerialNumber"];
```

```
// Display the serial number.
printf("SerialNumber: %s\n", $SerialNumber);

// Determine whether we are running as demo or trial.
if ((1111110000 <= $SerialNumber) and ($SerialNumber <= 1111119999))
    printf("This is a stock demo or trial license.\n");
  else
    printf("This is not a stock demo or trial license.\n");
```

VB.NET

```
' Shows how to obtain the serial number of the active license, and determine whether it
is a stock demo or trial license.

Imports OpcLabs.EasyOpc.UA

Namespace UADocExamples.Licensing

        Public Shared Sub SerialNumber()

            ' Instantiate the client object.
            Dim client = New EasyUAClient()

            ' Obtain the serial number from the license info.
            Dim serialNumber As Long =
CUInt(client.LicenseInfo("Multipurpose.SerialNumber"))

            ' Display the serial number.
            Console.WriteLine("SerialNumber: {0}", serialNumber)

            ' Determine whether we are running as demo or trial.
            If (1111110000 <= serialNumber) And (serialNumber <= 1111119999) Then
                Console.WriteLine("This is a stock demo or trial license.")
            Else
                Console.WriteLine("This is not a stock demo or trial license.")
            End If
        End Sub
    End Class
End Namespace
```

13.2.1.2 Examples - Licensing - Register managed resource

The example below shows how to register a license located in an embedded managed resource.

C#

```
// Shows how to register a license located in an embedded managed resource.

using System;
using System.Reflection;
using OpcLabs.BaseLib.ComponentModel;
using OpcLabs.EasyOpc.UA;
```

```
namespace UADocExamples.Licensing
{
    class _LicensingManagement
    {
        public static void RegisterManagedResource()
        {
            // Register a license that is we embed as a managed resource in this
program.

            // The first two arguments should always be "QuickOPC" and "Multipurpose".
            // The third argument determines the assembly where the license resides.
            // The fourth argument is the namespace-qualified name of the managed
resource.
            LicensingManagement.Instance.RegisterManagedResource("QuickOPC",
"Multipurpose",
                Assembly.GetExecutingAssembly(),
                "UADocExamples.Licensing.Key-DemoOrTrial-WebForm-1999003494-
20180611.bin");

            // Instantiate the client object, obtain the serial number from the license
info, and display the serial number.
            var client = new EasyUAClient();
            long serialNumber = (uint)client.LicenseInfo["Multipurpose.SerialNumber"];
            Console.WriteLine("SerialNumber: {0}", serialNumber);

            // The license we ship for this purpose is a trial license with low runtime
limit, so it won't be of much use.
            // But you get the point...
        }
    }
}
```

VB.NET

```
' Shows how to register a license located in an embedded managed resource.

```

13.2.2 Examples - Live Mapping

13.2.2.1 Examples - Live Mapping - Define OPC Data Access type-less mapping and read

The example below shows how to define a new type-less mapping which maps a specified OPC-DA item to the Value member of your target MyClass object. The mapper is then instructed to invoke the OPC read operation, which will in turn store the OPC item's value to your target object.

Type-less mapping (OPC DA) in C#

```
var mapper = new DAClientMapper();
var target = new MyClass2();

// Define a type-less mapping.

mapper.DefineMapping(
     new DAClientItemSource("OPCLabs.KitServer.2", "Simulation.Register_I4",
DADataSource.Cache),
     new DAClientItemMapping(typeof(Int32)),
     new ObjectMemberLinkingTarget(target.GetType(), target, "Value"));

// Perform a read operation.
mapper.Read();
```

Type-less mapping (OPC DA) in VB.NET

```
Public Shared Sub Main1()
    Dim mapper = New DAClientMapper()
    Dim target = New MyClass2()
```

```
    ' Define a type-less mapping.

    mapper.DefineMapping( _
             New DAClientItemSource( _
                 "OPCLabs.KitServer.2",
                 "Simulation.Register_I4",
                 New DAReadParameters(DADataSource.Cache)),
             New DAClientItemMapping(GetType(Int32)),
             New ObjectMemberLinkingTarget(target.GetType(), target, "Value"))

    ' Perform a read operation.
    mapper.Read()

    ' Display the result.
    Console.WriteLine(target.Value)
End Sub
```

13.2.2.2 Examples - Live Mapping - Define OPC Unified Architecture type-less mapping and read

The example below shows how to define a new type-less mapping which maps a specified node in OPC Unified Architecture (OPC-UA) server to the Value member of your target MyClass2 object. The mapper is then instructed to invoke the OPC read operation, which will in turn store the OPC node's value to your target object:

Type-less mapping (OPC UA) in C#

```
UAEndpointDescriptor endpointDescriptor =
    "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
// or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
// or "https://opcua.demo-this.com:51212/UA/SampleServer/"

var mapper = new UAClientMapper();
var target = new MyClass2();

// Define a type-less mapping.

MemberInfo memberInfo = target.GetType().GetMember("Value").SingleOrDefault();
Debug.Assert(memberInfo != null);

mapper.DefineMapping(
    new UAClientDataMappingSource(
        endpointDescriptor,
        "nsu=http://test.org/UA/Data/;i=10389",
        UAAttributeId.Value,
        UAIndexRangeList.Empty,
```

```
        UAReadParameters.CacheMaximumAge),
    new UAClientDataMapping(typeof(Int32)),
    new ObjectMemberLinkingTarget(target.GetType(), target, memberInfo));

// Perform a read operation.
mapper.Read();
```

Type-less mapping (OPC UA) in VB.NET

```
Public Shared Sub Main1()

    ' Define which server we will work with.
    Dim endpointDescriptor As UAEndpointDescriptor =
            "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer"
    ' or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
    ' or "https://opcua.demo-this.com:51212/UA/SampleServer/"

    Dim mapper = New UAClientMapper()
    Dim target = New MyClass2()

    ' Define a type-less mapping.

    Dim memberInfo = target.GetType().GetMember("Value").SingleOrDefault()
    Debug.Assert(memberInfo IsNot Nothing)

    mapper.DefineMapping( _
        New UAClientDataMappingSource( _
            endpointDescriptor, _
            "nsu=http://test.org/UA/Data/;i=10389", _
            UAAttributeId.Value, _
            UAIndexRangeList.Empty, _
            UAReadParameters.CacheMaximumAge), _
        New UAClientDataMapping(GetType(Int32)), _
        New ObjectMemberLinkingTarget(target.GetType(), target, memberInfo))

    ' Perform a read operation.
    mapper.Read()

    ' Display results
    Console.WriteLine(target.Value)
End Sub
```

13.2.2.3 Examples - Live Mapping - Subscribe and subscribe with OPC Data Access type-less mapping

The example below shows how to subscribe and unsubscribe:

Subscribe and subscribe with type-less mapping in C#

```
// This example for OPC DA type-less mapping shows how to define a mapping and perform
subscribe and unsubscribe operations.

using System;
using System.Threading;
using OpcLabs.BaseLib.ComponentModel.Linking;

```
// This example shows how to subscribe to changes of a single item and display the
value of the item with each change.
//
// Some related documentation: http://php.net/manual/en/function.com-event-sink.php .
Pay attention to the comment that says
// "Be careful how you use this feature; if you are doing something similar to the
example below, then it doesn't really make
// sense to run it in a web server context.". What they are trying to say is that
processing a web request should be
// a short-lived code, which does not fit well with the idea of being subscribed to
events and received them over longer time.
// It is possible to write such code, but it is only useful when processing the request
is allowed to take relatively long. Or,
// when you are using PHP from command-line, or otherwise - not to serve a web page
directly.
//
// Subscribing to QuickOPC-COM events in the context of PHP Web application, while not
imposing the limitations to the request
// processing time, has to be "worked around", e.g. using the "event pull" mechanism.
```

```
class DEasyDAClientEvents {
    function ItemChanged($varSender, $varE)
    {
        if ($varE->Succeeded)
        {
        print $varE->Vtq->ToString();
            print "\n";
        }
        else
        {
            printf("*** Failure: %s\n", $varE->ErrorMessageBrief);
        }
    }
}

$Client = new COM("OpcLabs.EasyOpc.DataAccess.EasyDAClient");

13.2.8 Examples - OPC UA Complex Data

13.2.8.1 Examples - OPC UA Complex Data - Create a data type

C#

```
StructuredDataType structuredDataType = new StructuredDataType(
        "ControllerConfiguration",

"urn:UnifiedAutomation:CppDemoServer:BuildingAutomation:ControllerConfiguration")
    {
        new DataField("Name", UAOpcBinaryStandardDataTypes.CharArray),
        new DataField("DeviceAddress", UAOpcBinaryStandardDataTypes.UInt32),
        new DataField("TemperatureSetpoint", UAOpcBinaryStandardDataTypes.Double)
    };
```

Notice the use of pre-defined primitive types from the UAOpcBinaryStandardDataTypes Class. It is common to encounter references to standard data types from OPC Binary data type system, and the OPC UA Complex Data extension gives you this class so that you can refer to them easily.

13.2.8.2 Examples - OPC UA Complex Data - Create generic data

The example below shows how different kinds of generic data can be created.

C#

```
// This example shows different ways of constructing generic data.

using System;
using System.Collections;
using OpcLabs.BaseLib.DataTypeModel;

namespace UADocExamples.ComplexData._GenericData
{
    class _Construction
    {
        public static void Main1()
        {
            // Create enumeration data with value of 1.
            var enumerationData = new EnumerationData(1);
```

```
            Console.WriteLine(enumerationData);

            // Create opaque data from an array of 2 bytes, specifying its size as 15
bits.
            var opaqueData1 = new OpaqueData(new byte[] {0xAA, 0x55}, sizeInBits:15);
            Console.WriteLine(opaqueData1);

            // Create opaque data from a bit array.
            var opaqueData2 = new OpaqueData(new BitArray(new[] { false, true, false,
true, false }));
            Console.WriteLine(opaqueData2);

            // Create primitive data with System.Double value of 180.0.
            var primitiveData1 = new PrimitiveData(180.0d);
            Console.WriteLine(primitiveData1);

            // Create primitive data with System.String value.
            var primitiveData2 = new PrimitiveData("Temperature is too high!");
            Console.WriteLine(primitiveData2);

            // Create sequence data with two elements, using collection initializer
syntax.
            var sequenceData1 = new SequenceData
            {
                opaqueData1,
                opaqueData2
            };
            Console.WriteLine(sequenceData1);

            // Create the same sequence data, using the Add method.
            var sequenceData2 = new SequenceData();
            sequenceData2.Elements.Add(opaqueData1);
            sequenceData2.Elements.Add(opaqueData2);
            Console.WriteLine(sequenceData2);

            // Create the same sequence data, using an array (an enumerable) of its
elements.
            var sequenceData3 = new SequenceData(

            var client = new EasyUAClient();

            // Obtain the data type ID.
            //
            // In many cases, you would be able to obtain the data type ID of a particular node by reading its
DataType
            // attribute, or easier, by calling the extension method ReadDataType on the IEasyUAClient interface.
The sample
            // server, however, shows a more advanced approach in which the data type ID refers to an abstract
data type,
            // and the actual values are then sub-types of this base data type. This abstract data type does not
have any
            // encodings associated with it and it is therefore not possible to extract its description from the
server.
            // We therefore use a hard-coded data type ID for one of the sub-types in this example.
            //
            // The code to obtain the data type ID for given node would normally look like this:
            //    UANodeId dataTypeId = client.ReadDataType(
            //        endpointUriString,
            //        "nsu=http://test.org/UA/Data/;i=10239");    //

13.2.8.8 Examples - OPC UA Complex Data - Resolve a data type

The example below shows how to resolve a data type. The main work is done by the ResolveDataType Method.

C#

```
// Shows how to obtain object describing the data type of complex data node with OPC UA Complex
Data plug-in.

using System;
using OpcLabs.BaseLib.DataTypeModel;
using OpcLabs.BaseLib.Extensions;
using OpcLabs.BaseLib.OperationModel.Generic;
using OpcLabs.EasyOpc.UA;
using OpcLabs.EasyOpc.UA.AddressSpace;
using OpcLabs.EasyOpc.UA.AddressSpace.Standard;
using OpcLabs.EasyOpc.UA.InformationModel;
using OpcLabs.EasyOpc.UA.Plugins.ComplexData;
```

```
namespace UADocExamples.ComplexData._IEasyUAClientComplexData
{
    class ResolveDataType
    {
        public static void Main1()
        {
            // Define which server we will work with.
            UAEndpointDescriptor endpointDescriptor =
                "opc.tcp://opcua.demo-this.com:51210/UA/SampleServer";
            // or "http://opcua.demo-this.com:51211/UA/SampleServer" (not in .NET Standard)
            // or "https://opcua.demo-this.com:51212/UA/SampleServer/"

            // Instantiate the client object.
            var client = new EasyUAClient();

            // Obtain the data type ID.
            //
            // In many cases, you would be able to obtain the data type ID of a particular node by
reading its DataType
            // attribute, or easier, by calling the extension method ReadDataType on the
IEasyUAClient interface.
            // The sample server, however, shows a more advanced approach in which the data type ID
refers to an abstract
            // data type, and the actual values are then sub-types of this base data type. This
abstract data type does not
            // have any encodings associated with it and it is therefore not possible to extract
its description from the
            // server. We therefore use a hard-coded data type ID for one of the sub-types in this
example.
            //
            // The code to obtain the data type ID for given node would normally look like this:
            //    UANodeId dataTypeId = client.ReadDataType(
            //        endpointDescriptor,
            //        "nsu=http://test.org/UA/Data/;i=10239");    //
[ObjectsFolder]/Data.Static.Scalar.StructureValue
            //
            UANodeId dataTypeId = "nsu=http://test.org/UA/Data/;i=9440";    // ScalarValueDataType

            // Get the IEasyUAClientComplexData service from the client. This is needed for
advanced complex data
            // operations.
            IEasyUAClientComplexData complexData = client.GetService<IEasyUAClientComplexData>();

            // Resolve the data type ID to the data type object, containing description of the data
type.
            ValueResult<DataType> dataTypeResult = complexData.ResolveDataType(
                new UAModelNodeDescriptor(endpointDescriptor, dataTypeId),
                UABrowseNames.DefaultBinary);
            // Check if the operation succeeded. Use the ThrowIfFailed method instead if you want
exception be thrown.
            if (!dataTypeResult.Succeeded)
            {
                Console.WriteLine("*** Failure: {0}", dataTypeResult.ErrorMessageBrief);
                return;
            }

            // The actual data type is in the Value property.
            // Display basic information about what we have obtained.
            Console.WriteLine(dataTypeResult.Value);

            // If we want to see the whole hierarchy of the received data type, we can format it
with the "V" (verbose)
            // specifier. In the debugger, you can view the same by displaying the private
DebugView property.
            Console.WriteLine();
```

```
            Console.WriteLine("{0:V}", dataTypeResult.Value);

            // For processing the internals of the data type, refer to examples for GenericData
class.

            // Example output (truncated):
            //
            //ScalarValueDataType = structured
            //
